SNAP CODES: (See below)

# SOURCE ACTIVITY TITLE: COMBUSTION IN ENERGY & TRANSFORMATION INDUSTRIES Combustion Plants as Point Sources

The following activities are taken into account, when treating combustion plants individually as point sources.

Combustion plants with a thermal capacity < 300 MW, gas turbines and stationary engines, which may also be considered collectively as area sources, are covered by chapter B112 "Combustion Plants as Area Sources" as well.

# 1 ACTIVITIES INCLUDED

This chapter covers emissions from boilers, gas turbines and stationary engines as point sources. According to CORINAIR90, combustion plants with

- a thermal capacity ≥ 300 MW
- or
- emissions of SO<sub>2</sub> or NO<sub>x</sub> or NMVOC > 1,000 Mg/a<sup>1</sup>

should be considered as point sources /41/. Within CORINAIR other combustion plants may also be considered as point sources on a voluntary basis. Different criteria are applied for the classification of combustion plants according to the Large Combustion Plant Directive (88/609/EEC)<sup>2</sup> /9, 42/.

Boilers, gas turbines and stationary engines need to be treated separately (see table at start of this chapter). With regard to boilers, a combustion plant may consist of one single boiler or may comprise a series of boilers of different sizes (joint plant). Therefore, whenever there is more than one boiler on a site, a decision on the aggregation of these facilities to plants has to be taken. Through this decision, an allocation to the respective SNAP categories is achieved. For aggregation criteria see Section 3.2 and Annex 1.

The subdivision of SNAP activities according to CORINAIR90 concerning combustion plants takes into account two criteria:

- a) the economic sector concerning the use of energy
  - public power and co-generation,
  - district heating,
  - commercial and institutional combustion,
  - industrial combustion in boilers,

(Note: Process furnaces are allocated separately.)

<sup>&</sup>lt;sup>1</sup> For  $CO_2$  a further optional criterion for point sources is the emission of > 300 Gg/a.

The Large Combustion Plant Directive covers combustion plants with a thermal capacity  $\geq$  50 MW in the EU. Gas turbines and stationary engines are excluded. Existing plants with a thermal capacity > 300 MW have to be reported as point sources on an individual basis.

- b) the technical characteristics
  - with respect to boilers, the installed thermal capacity,
    - $\ge 300 \text{ MW},$
    - $\ge 50 \text{ to} < 300 \text{ MW},$
    - $\le 50 \text{ MW}$ ,
  - other combustion technologies,
    - gas turbines,
    - stationary engines.

Emissions considered in this section are released by a controlled combustion process (boiler emissions, emissions from the combustion chamber of gas turbines or stationary engines), taking into account primary reduction measures, such as furnace optimisation inside the boiler or the combustion chamber, and secondary reduction measures downstream of the boiler or the combustion chamber. Solid, liquid or gaseous fuels are used, where solid fuels comprise coal, coke, biomass and waste (as far as waste is used to generate heat or power). In addition, a non-combustion process can be a source of ammonia emissions, namely ammonia slip in connection with several  $NO_x$  abatement techniques.

# 2 CONTRIBUTION TO TOTAL EMISSIONS

This section covers emissions of SO<sub>x</sub>, NO<sub>x</sub>, CO, CO<sub>2</sub>, NMVOC, CH<sub>4</sub>, N<sub>2</sub>O, NH<sub>3</sub> and heavy metals (As, Cd, Cr, Cu, Hg, Ni, Pb, Se, Zn, V). The contributions of point source emissions released by combustion plants to the total emissions in countries of the CORINAIR90 inventory are given as follows in Table 1:

**Table 1:** Contributions of emissions from combustion plants <u>as point sources</u> to total emissions of the CORINAIR90 inventory reported as point sources

			Contribution to total emissions [%]						
Source category	SNAP90 code	$SO_2$	$NO_x$	NMVOC	CH <sub>4</sub>	СО	CO <sub>2</sub>	N <sub>2</sub> O	NH <sub>3</sub>
≥ 300 MW	01 01 01 01 02 01 03 01 01	85.6	81.4	10.2	5.5	16.8	79.0	35.7	2.4

<sup>-:</sup> no emissions are reported

In the literature concerning heavy metal emissions across Europe, point source emissions are not reported separately. Giving an order of magnitude of heavy metal emissions released from combustion plants emission data of coal-fired public power plants in Germany and Austria is presented here as an example, due to the availability of data:

**Table 2:** Contributions of heavy metal emissions from coal-fired public power plants to national total emissions of Germany<sup>1)</sup> /36/

	Contribution in [wt%]				
Pollutant	1982	1990			
As	38	27			
Cd <sup>2)</sup>	7	7			
Cr	12	4			
Cu	22	8			
Hg <sup>3)</sup>	11	14			
Ni	5	4			
Pb	8	1			
Se	1	1			
Zn	7	6			

Western part of Germany

By comparing the heavy metal emissions in 1982 (without flue gas desulphurisation (FGD) installed) to the emissions in 1990 (where most plants are equipped with FGD), it can be seen that the application of FGD technologies has lead to a significant decrease in heavy metal emissions within the last years.

<sup>0:</sup> emissions are reported, but the precise number is under the rounding limit

Gas turbines and stationary engines may be reported either as point or as area sources.

E.g. emissions of Cd in Austria in 1992 were 0,2 % /37/.

E.g. emissions of Hg in Austria in 1992 were 6 % /37/.

#### 3 **GENERAL**

#### 3.1 **Description**

The emissions considered in this chapter are generated either by boilers or by gas turbines and stationary engines regardless of the allocation of plants to SNAP activities. Emissions from process furnaces (combustion with contact) and from waste incineration are not included here (therefore see SNAP code 090200).

#### 3.2 **Definitions**

as received, a reference state of coal which determines the ar

conditions, when coal arrives at the plant /73/.

**Availability** ratio of full load operating hours with operating emission control technology to total full load operating hours of the (of an abatement technology)

power plant; the availability  $\beta$  normally amounts to 99 %; but extreme low values of  $\beta$  can occur down to 95 %. By taking into account the start-up behaviour of emission reduction technologies, the availability  $\beta$  can decrease

further down to 92 %. Default values are proposed in Tables

7 and 11.

**Boiler** any technical apparatus, in which fuels are oxidised in order

to generate heat for locally separate use.

Coking coal (NAPFUE 101) subcategory of hard coal with a quality that allows the

production of a coke suitable for supporting a blast furnace

charge /114/.

Co-generation plant steam production in boilers (one or more boilers) for both,

power generation (in a steam turbine) and heat supply.

(CCGT)

Combined Cycle Gas Turbine gas turbine combined with a steam turbine. The boiler can

also be fuelled separately.

daf dry and ash free, a reference state of coal which is calculated

> with reference to a theoretical base of no moisture or ash associated with the sample (equivalent to maf - moisture and

ash free) /73/.

Hard coal refers to coal of a gross caloric value greater than 23,865

> kJ/kg on an ash-free but moist basis and with a mean random reflectance<sup>3</sup> of vitrinite of at least 0.6. Hard coal comprises

the subcategories coking coal and steam coal<sup>4</sup> /114/.

<sup>&</sup>lt;sup>3</sup> Mean random reflectance: characteristic value, which stands for a defined coal composition (modular component is e.g. vitrinite).

The following coal classification codes cover those coals, which would fall into these subcategories /114/:

Combined Cycle Gas Turbine gasification process. (IGCC)

Integrated Coal Gasification gas turbine fuelled by gas, which is a product of a coal

Lignite (NAPFUE 105)

non-agglomerating coals with a gross caloric value less than 17,435 kJ/kg and containing more than 31 % volatile matter on a dry mineral matter free basis /114/.

maf

moisture and ash free, a reference state of coal (equivalent to daf - dry and ash free) /73/.

Plant/Joint Plant

classification with respect to boilers (one or more boilers) according to the respective boiler configuration on a given site and the applied concept of aggregation. The stack-bystack principle considers all boilers linked to the same stack as a common plant. On the other hand, according to the virtual stack principle, all boilers which, for technical and economic reasons, could be connected to a common stack, are treated as one unit. It is also possible to carry out a still broader combination following e.g. administrative aspects. Gas turbines and stationary engines are allocated separately. A typical example of different allocation possibilities of boilers to the SNAP codes is given in Annex 1.

Power plant

steam generation in boilers (one or more boilers) for power generation.

Reduction efficiency (of an abatement technology)

difference between the pollutant concentration in the raw gas  $(c_{raw})$  and the pollutant concentration in the clean gas  $(c_{clean})$ divided by the pollutant concentration in the raw gas (referred to full load operating hours); default values for the reduction efficiency  $\eta = (c_{raw} - c_{clean})/c_{raw}$  of different emission control technologies are recommended in Tables 7 and 11 (extreme low values of  $\eta$  can be up to ten percent below the values given).

Start-up emission

here start-up emissions have been considered for boilers equipped with secondary measures: For SO<sub>2</sub> and NO<sub>2</sub> from the time when burners switch on up to the time when the

Australian classification Class 4A, 4B, 5.

Activities 010101 - 010105

secondary abatement facility operates under optimum conditions; for CO up to the time when the boiler operates at

minimum load.

Stationary engines spark-ignition or compression-ignition engines (2- and 4-

stroke).

Steam coal (NAPFUE 102) subcategory of hard coal used for steam raising and space

heating purposes. Steam coal includes all anthracite and

bituminous coals not included under coking coal /114/.

Sub-bituminous coal (NAPFUE 103)

non-agglomerating coals with a gross caloric value between 17,435 and 23,865 kJ/kg containing more than 31 % volatile

matter on a dry mineral free matter basis /114/

Sulphur retention in ash difference between the sulphur dioxide concentration

calculated from the total sulphur content of fuel  $(c_{max})$  and the sulphur dioxide concentration of the flue gas  $(c_{eff})$  divided by the sulphur dioxide concentration calculated from the total sulphur content of the fuel. Default values for the sulphur retention in ash  $\alpha_s = (c_{max} - c_{eff})/c_{max}$  are proposed in

Table 8.

# 3.3 Techniques

# 3.3.1 Combustion of coal

# 3.3.1.1 Dry bottom boiler (DBB)

The DBB is characterised by the dry ash discharge from the combustion chamber due to combustion temperatures from 900 up to 1,200 °C. This type of boiler is mainly used for the combustion of hard coal and lignite and is applied all over Europe.

# 3.3.1.2 Wet bottom boiler (WBB)

Typical combustion temperatures exceeding  $1,400\,^{\circ}\text{C}$  lead to a liquid slag discharge from the combustion chamber. This type of boiler is used for hard coal with a low content of volatiles and is mainly applied in Germany.

# 3.3.1.3 Fluidised bed combustion (FBC)

The combustion of coal takes place by injection of combustion air through the bottom of the boiler into a turbulent bed. The typical relatively low emissions are achieved by air staging, limestone addition and low combustion temperatures of about 750 - 950 °C. FBC is in particular adapted to coals rich in ash. Only few large combustion plants are equipped with the FBC technique; in the category of thermal capacities  $\geq$  300 MW mostly Circulating Fluidised Bed Combustion (CFBC) is installed.

# 3.3.1.4 Grate Firing (GF)

The lump fuel (coal, waste) is charged on a stationary or slowly moving grate. The combustion temperatures are mainly between 1,000 and 1,300 °C.

#### **3.3.2** Combustion of biomass

The combustion of biomass (peat, straw, wood) is only relevant for some countries (e.g. Finland, Denmark). FBC (mostly CFBC) and DBB facilities are installed.

#### 3.3.3 Combustion of waste

For the combustion of waste, mostly grate firing installations are in use.

# 3.3.4 Combustion of gas/oil

# 3.3.4.1 Combustion in boilers (general aspects of the combustion techniques)

For both, gas and oil combustion, the fuel and oxidising agents are gaseous under combustion conditions. The main distinctions between gas/oil combustion and pulverised coal combustion are the operation designs of the individual burners of the boiler. With respect to emissions, a principal distinction can be made between burners with and without a pre-mix of fuel and combustion air: pre-mixing burners are characterised by a homogeneous short flame and a high conversion rate of fuel bound nitrogen; non-pre-mixing burners are characterised by inhomogeneous flames with understoichiometric reaction zones and a lower conversion rate of fuel bound nitrogen.

The importance of oil and gas combustion considered as point sources (see Section 1) is low compared to coal combustion, due to the smaller total capacity of these installations. The main parameters determining emissions from oil and gas fired plants are given in Table 3.

#### 3.3.4.2 Gas turbines

Gas turbines are installed with a thermal capacity ranging from several hundred kW up to 500 MW. Gaseous fuels are mainly used, such as natural gas or the product of coal gasification (e.g. CCGT or IGCC installations) or other process gases. Also liquid fuels are used, such as light distillates (e.g. naphtha, kerosene or fuel oil) and in some cases other fuels (e.g. heavy fuel oil). Combustion temperatures of up to 1,300  $^{\circ}$ C in the combustion chambers may lead to considerable NO<sub>x</sub> emissions.

Gas turbines are installed as a part of different types of combustion plants such as Combined Cycle Gas Turbine (CCGT) or Integrated Coal Gasification Combined Cycle Gas Turbine (IGCC) Plants (see also Section 3.2). For IGCC plants, the only emission relevant unit considered here is the gas turbine (combustion chamber). For CCGT, in addition to the gas turbine any installed fossil fuelled boiler should also be taken into account.

# 3.3.4.3 Stationary engines

Stationary engines are installed as spark-ignition engines and compression-ignition engines (2- and 4-stroke) with electrical outputs ranging from less than 100 kW to over 10 MW (e.g. in co-generation plants) /cf. 46/. Both types represent relevant emission sources.

#### 3.4 Emissions

Relevant pollutants are sulphur oxides  $(SO_x)$ , nitrogen oxides  $(NO_x)$ , carbon dioxide  $(CO_2)$  and heavy metals (arsenic (As), cadmium (Cd), chromium (Cr), copper (Cu), mercury (Hg), nickel (Ni), lead (Pb), selenium (Se), zinc (Zn) and in the case of heavy oil also vanadium (V)). Emissions of volatile organic compounds (non-methane VOC and methane (CH<sub>4</sub>)), nitrous oxide (N<sub>2</sub>O), carbon monoxide (CO) and ammonia (NH<sub>3</sub>) are of less importance. For species profiles of selected pollutants see section 9.

The emissions are released through the stack. Fugitive emissions (from seals etc.) can be neglected for combustion plants.

The emissions of sulphur oxides (SO<sub>x</sub>) are directly related to the sulphur content of the fuel, which for coal normally varies between 0.3 and 1.2 wt.-% (maf) (up to an extreme value of 4.5 wt.-%) and for fuel oil (including heavy fuel oil) from 0.3 up to 3.0 wt.-% /15, 16/; usually, the sulphur content of gas is negligible. Sulphur appears in coal as pyritic sulphur (FeS<sub>2</sub>), organic sulphur, sulphur salts and elemental sulphur. A major part of the sulphur in coal comes from pyritic and organic sulphur; both types are responsible for SO<sub>x</sub> formation. The total sulphur content of coal is usually determined by wet chemical methods; by comparison with results from the X-ray method, it has been found that standard analytical procedures may overestimate the organic sulphur content of coal /30/. The uncertainty introduced by the analytical procedures should be determined by further research.

For nitric oxide (NO, together with  $NO_2$  normally expressed as nitrogen oxides  $NO_x$ ) three different formation mechanisms have to be distinguished (see also Section 9):

- -formation of "fuel-NO" from the conversion of chemically bound nitrogen in the fuel (NO<sub>fuel</sub>),
- -formation of "thermal-NO" from the fixation of atmospheric nitrogen coming from the combustion air  $(NO_{thermal})$ ,
- -formation of "prompt-NO".

In the temperature range considered (up to 1,700 °C) the formation of "prompt6-NO" can be neglected. The majority of  $NO_x$  emissions from coal combustion (80 to more than 90 %) is formed from fuel nitrogen. Depending on combustion temperatures, the portion of thermal- $NO_x$  formed is lower than 20 %. The content of nitrogen in solid fuels varies: for hard coal between 0.2 and 3.5 wt.-% (maf), for lignite between 0.4 and 2.5 wt.-% (maf), for coke between 0.6 and 1.55 wt.-% (maf), for peat between 0.7 and 3.4 wt.-% (maf), for wood between 0.1 and 0.3 wt.-% (maf), and for waste between 0.3 and 1.4 wt.-% (maf) /17/. The content of nitrogen in liquid fuels varies for heavy fuel oil between 0.1 and 0.8 wt.-%, and for fuel oil between 0.005 and 0.07 wt.-% /17/. Natural gas contains no organically bound nitrogen. The content of molecular nitrogen in natural gas has no influence on the formation of fuel-NO; only thermal-NO is formed.

Emissions of non-methane volatile organic compounds (NMVOC), e.g. olefins, ketones, aldehydes, result from incomplete combustion. Furthermore, unreacted fuel compounds such as methane (CH<sub>4</sub>) can be emitted. The relevance of NMVOC/CH<sub>4</sub> emissions from boilers, which are often reported together as VOC, is very low for large-sized combustion plants. VOC emissions tend to decrease as the plant size increases (cf. /24/).

Carbon monoxide (CO) appears always as an intermediate product of the combustion process and in particular under understoichiometric combustion conditions. However, the relevance of CO released from combustion plants is not very high compared to CO<sub>2</sub>. The formation mechanisms of CO, thermal-NO and VOC are similarly influenced by combustion conditions.

Carbon dioxide  $(CO_2)$  is a main product from the combustion of all fossil fuels. The  $CO_2$  emission is directly related to the carbon content of fuels. The content of carbon varies for hard and brown coal between 61 and 87 wt.-% (maf), for wood it is about 50 wt.-% and for gas oil and heavy fuel oil about 85 wt.-%.

The formation mechanism of nitrous oxide ( $N_2O$ ) has not yet been completely clarified. There is a possible formation mechanism based on intermediate products (HCN, NH<sub>3</sub>), which is comparable to the formation of NO /55/. It has been found, that lower combustion temperatures, particularly below 1,000 °C, cause higher  $N_2O$  emissions /13/. At lower temperatures the  $N_2O$  molecule is relatively stable; at higher temperatures the  $N_2O$  formed is reduced to  $N_2$  /55/. Compared to emissions from conventional stationary combustion units, nitrous oxides from either bubbling, circulating or pressurised fluidised bed combustion are relatively high /13, 14/. In laboratory experiments, it has been found that nitrous oxide is formed by Selective Catalytic Reduction (SCR) processes, passing a maximum at, or close to, the optimum temperature "window" of the SCR process /13/.

Emissions of ammonia (NH<sub>3</sub>) are not caused by a combustion process; the emissions result from incomplete reaction of NH<sub>3</sub> additive in the denitrification process (slip of ammonia in SCR and SNCR units).

Most of the heavy metals considered (As, Cd, Cr, Cu, Hg, Ni, Pb, Se, Zn, V) are normally released as compounds (e.g. oxides, chlorides) in association with particulates. Only Hg and Se are at least partly present in the vapour phase. Less volatile elements tend to condense onto the surface of smaller particles in the flue gas stream. Therefore, an enrichment in the finest particle fractions is observed. The content of heavy metals in coal is normally several orders of magnitude higher than in oil (except occasionally for Ni and V in heavy fuel oil) and in natural gas. For natural gas only emissions of mercury are relevant. The concentrations are reported to be in the range of 2 - 5  $\mu$ g/m³ for natural gas /35, 63/. During the combustion of coal, particles undergo complex changes which lead to vaporisation of volatile elements. The rate of volatilisation of heavy metal compounds depends on fuel characteristics (e.g. concentrations in coal, fraction of inorganic components, such as calcium) and on technology characteristics (e.g. type of boiler, operation mode).

From DBB, all heavy metals of concern are emitted as particulate matter, except Hg and Se. Emissions from lignite fired DBB are potentially lower than from hard coal, as the trace element content in lignite and the combustion temperatures are lower. In WBB, the recirculation of fly ash is a common operation mode, which creates an important increase in heavy metal concentrations in the raw gas. Heavy metal emissions from FBC units are expected to be lower due to the lower operating temperatures and a smaller fraction of fine particles. The addition of limestone in FBC facilities might reduce the emission of some heavy metals, corresponding to an increased retention of heavy metals in the bottom ash. This effect can be partially compensated by the increase in the fraction of fine particulates in the flue gas leading to increased emissions from particulates highly enriched by heavy metals.

High concentrations of As poison denitrification catalysts. Therefore, Selected Catalytic Reduction plants (SCR) in a high-dust configuration may require special measures (e.g. reduction of fly ash recirculation). /10, 11, 12/

#### 3.5 Controls

Relevant abatement technologies for  $SO_x$ ,  $NO_x$  and heavy metals are outlined below. Abatement techniques for gas turbines and stationary engines are treated separately. Average reduction efficiencies and availabilities of abatement technologies for  $SO_x$  and  $NO_x$  are summarised in Tables 7, 10, and 11. Due to the fact, that most published studies do not clearly distinguish between  $SO_x$  and  $SO_2$ , for the following chapters, it can be assumed that  $SO_2$  includes  $SO_3$ , if not stated otherwise.

# 3.5.1 Sulphur oxides: Flue Gas Desulphurisation Processes (FGD) (Secondary measures) /cf. 18/

FGD processes are designed to remove SO<sub>2</sub> from the flue gas of combustion installations. Most processes, like the wet scrubbing process (WS), the spray dryer absorption (SDA), the dry sorbent injection (DSI) and the Walther process (WAP) are based on the reaction of the SO<sub>2</sub> with an alkaline agent added as solid or as suspension/solution of the agent in water to

form the respective salts. In secondary reactions also  $SO_3$ , fluorides and chlorides are removed. In the case of the DESONOX process (see Section 3.5.4.2), the  $SO_2$  is catalytically oxidised to  $SO_3$  and reacts with water to form sulphuric acid. The Activated Carbon process (see Section 3.5.4.1) and the Wellman-Lord process remove the  $SO_2$  to produce a  $SO_2$  rich gas, which may be further processed to sulphur or sulphuric acid.

# 3.5.1.1 Lime/Limestone Wet Scrubbing (WS)

The pollutants are removed from the flue gas by chemical reactions with an alkaline liquid (suspension of calcium compounds in water). The main product is gypsum. The WS process represents about 90 % of the total FGD-equipped electrical capacity installed in European OECD countries. Facilities are in operation at combustion units using hard coal, lignite and oil with sulphur contents from about 0.8 to more than 3.0 wt.-%. Other fossil fuels (such as peat) are presently rarely used at combustion plants with a thermal capacity  $\geq$  300 MW. The SO<sub>2</sub> reduction efficiency is > 90 %.

# 3.5.1.2 Spray Dryer Absorption (SDA)

The SDA process removes the pollutant components from flue gas of fossil fired combustion units by injection of  $Ca(OH)_2$ . The process forms a dry by-product ( $CaSO_3 \cdot 1/2 H_2O$ ). This technology covers about 8 % of the total FGD-equipped electrical capacity installed in the European OECD countries. The SDA process is mostly in use at hard coal fired combustion units (sulphur content of fuel up to 3 wt.-%). Recent pilot studies have shown that this technique is also operational with other fossil fuels (oil, lignite, peat). The  $SO_2$  reduction efficiency is > 90 %.

# 3.5.1.3 Dry Sorbent Injection (DSI, LIFAC Process)

The DSI process is based on a gas/solid reaction of the flue gas and a dry sorbent (e.g. lime/limestone, sodium hydrogen carbonate NaHCO<sub>3</sub>) inside the boiler. There are three different process types according to the injection point of the additive into the boiler (e.g. primary or secondary air, flame front). The by-products are a dry mixture of the respective salts (mostly CaSO<sub>4</sub>). Only few power plants (some 5 % of the total FGD-equipped electrical capacity installed in European OECD countries) are equipped with this technology due to its low SO<sub>2</sub> reduction efficiency of 40 - 50 %, which is not sufficient to meet the emission standards of some countries. DSI processes are presently in use for hard coal, lignite, oil and coal/oil fired boilers. The optimum reduction efficiency is obtained for the sulphur contents of fuel between 0.5 and 1.7 wt.-% (max. 2 wt.-%).

The LIFAC process is an advanced dry sorbent injection process using additional water injection in a separate reactor downstream of the boiler, in order to raise the reduction efficiency. Generally, the  $SO_2$  reduction efficiency is > 50 %. At present, the LIFAC process is used in one plant in Finland with a  $SO_2$  reduction efficiency of already 70 %.

#### 3.5.1.4 Wellman-Lord (WL)

The WL process is a regenerable FGD process, which uses the sodium sulphite  $(Na_2SO_3)/$  sodium bisulphite  $(NaHSO_3)$  equilibrium in order to remove  $SO_2$  from the flue gas. An  $SO_2$ -rich gas is obtained, which is used for the production of sulphuric acid. At present only three

installations with a total thermal capacity of 3,300 MW are in use (in Germany), due to the complexity of the process and the resulting high investments and operating costs (this technology represents about 3 % of the total thermal capacity installed in the European OECD countries). The WL process is operational with various types of fuel (e.g. hard coal, oil), especially with high sulphur contents (of about 3.5 wt.-%). The  $SO_2$  reduction efficiency is > 97 %.

# 3.5.1.5 Walther Process (WAP)

The WAP process uses ammonia water in order to remove  $SO_2$  from the flue gas. The by-product is a dry salt mixture of the respective ammonia salts (mainly ammonium sulphate  $((NH_4)_2SO_4)$ ). One reference installation is currently operating in Germany. This process is operational with all types of fuel. However, the maximum sulphur content should be limited to 2 wt.-% (due to the increasing formation of ammonia sulphate aerosols). The  $SO_2$  reduction efficiency is > 88 %.

# 3.5.2 Nitrogen oxides: Primary measures - Denitrification techniques /cf. 17, 18, 19/

# 3.5.2.1 Low $NO_x$ burner (LNB)

A characteristic of LNB is the staged air to fuel ratio at the burner. Three different technical modifications are in use:

- Air-staged LNB: An understoichiometric zone is created by a fuel-air mixture and primary air. An internal recirculation zone occurs due to the swirl of primary air. A burn-out zone is created due to secondary air fed by air nozzles arranged around the primary air nozzles.
- Air-staged LNB with flue gas recirculation (FGR): The basic function is similar to air-staged LNB. The distances between the primary and secondary nozzles are greater, therefore, a flue gas layer is formed. As a result, the residence time in the reducing atmosphere increases and the oxygen concentration decreases.
- Air/Fuel staged LNB: An additional reduction zone around the primary zone is achieved by the extremely overstoichiometric addition of secondary fuel around the secondary flame.

LNB is operational with all fuels and all types of burners. The  $NO_x$  reduction efficiency for coal fired boilers varies between 10 and 30 % (see Table 10).

# 3.5.2.2 Staged Air Supply (SAS)

Staged air means the creation of two divided combustion zones - a primary zone with a lack of oxygen and a burn-out zone with excess air. SAS covers the low excess air (LEA), burners out of service (BOOS) and biased burner firing (BBF) techniques:

- Low excess air (LEA) means reduction of the oxygen content in the primary combustion zone of the burners. When firing hard coal, experience has shown that the general limitations are fouling and corrosion, caused by the reducing atmosphere and incomplete burn-out. When firing gas, the reduction efficiency is limited by the CO formed. LEA is more suitable for lignite and often used for retrofitting combustion plants. For oil fired boilers a reduction efficiency of 20 % has been achieved.

- Burners out of service (BOOS) means that the lower burner row(s) in the boiler operate under a lack of oxygen (fuel rich), the upper burners are not in use. This technology is in particular suitable for older installations, but the thermal capacity of the boiler decreases by about 15 - 20 %.
- Biased burner firing (BBF) means that the lower burner rows in the boiler operate under a lack of oxygen (fuel rich) and the upper burners with an excess of oxygen. The boiler efficiency is less compared to BOOS and the NO<sub>x</sub> reduction is also lower.

The  $NO_x$  reduction efficiency for coal fired boilers varies between 10 and 40 % (see Table 10).

# 3.5.2.3 Overfire Air (OFA)

All burner rows in the boiler operate with a lack of oxygen. The combustion air is partly (5 - 20 %) injected through separate ports located above the top burner row in the boiler. OFA is operational with most fuels and most types of boilers. For gas fired boilers a reduction efficiency of 10 - 30 % and for oil fired boilers 10 - 40 % has been achieved. The  $NO_x$  reduction efficiency for coal fired boilers varies between 10 and 40 % (see Table 10).

# 3.5.2.4 Flue Gas Recirculation (FGR)

The recirculation of flue gas into the combustion air is an efficient  $NO_x$  abatement method for firing modes with high combustion temperatures, such as wet bottom boilers and especially for gas and oil fired boilers.

The recirculated flue gas can be added to the secondary or primary air. In the first case, the flame core is not affected and the only effect is a reduction of the flame temperature, which is favourable for thermal- $NO_x$  abatement. The influence on dry bottom boilers is thus very limited, considering the fact that about 80 % of the  $NO_x$  formed originates from fuel bound nitrogen; FGR can be used as an additional measure. A more efficient method is the introduction of flue gas into the primary air of an unstaged burner. High reduction efficiencies of FGR in the primary flow (15 - 20 %) have been achieved in gas and oil fired boilers. The  $NO_x$  reduction efficiency for coal fired boilers varies between 5 and 25 % (see Table 10).

# 3.5.2.5 Split Primary Flow (SPF)

Split primary flow means fuel staging in the furnace. This technique involves injecting fuel into the furnace above the main combustion zone, thereby producing a second understoichiometric combustion zone. In the primary zone of the boiler the main fuel is burnt under fuel-lean conditions. This zone is followed by a secondary zone with a reducing atmosphere, into which the secondary fuel is injected. Finally, secondary air is injected into the burn-out zone of the boiler. This reburning technique can, in principle, be used for all types of fossil fuel fired boilers and in combination with low  $NO_x$  combustion techniques for the primary fuels. When nitrogen is present in the reburning fuel, a part of it will be converted into  $NO_x$  in the burn-out zone. Therefore, natural gas is the most appropriate reburning fuel.  $NO_x$  reduction efficiencies have not been yet reported.

# 3.5.3 Nitrogen oxides: Secondary measures - Denitrification Processes /cf. 18, 19/

# 3.5.3.1 Selective Non-Catalytic Reduction (SNCR)

The reduction of nitrogen oxides in the flue gas is based on the selective reaction of  $NO_x$  with injected ammonia, urea or caustic ammonia to form nitrogen and water. The SNCR process has been implemented at several installations (e.g. in Germany, in Austria and in Sweden) and has in principle proved to be operational with various types of fuels. The  $NO_x$  reduction efficiency is about 50 %, in some installations up to 80 %.

# 3.5.3.2 Selective Catalytic Reduction (SCR)

The reduction of nitrogen oxides is based on selective reactions with injected additives in the presence of a catalyst. The additives used are mostly gaseous ammonia, but also liquid caustic ammonia or urea. The SCR technology accounts for about 95 % of all denitrification processes. SCR is mostly used for hard coal. For brown coal, lower combustion temperatures lead to lower  $NO_x$  formation, so that primary measures fulfil the emission reduction requirements. Several heavy metals in the flue gas can cause rapid deactivation of the catalyst. The  $NO_x$  reduction efficiency varies between 70 and 90 %.

# 3.5.4 Nitrogen oxides and sulphur oxides: Simultaneous Processes /18, 19/

# 3.5.4.1 Activated Carbon Process (AC)

The AC process is a dry process for simultaneous  $SO_2$  and  $NO_x$  removal based on the adsorption of the pollutants in a moving bed filter of activated carbon. The sulphur oxides undergo catalytic oxidation with the moisture in the flue gas to form sulphuric acid.  $NO_2$  is completely reduced to  $N_2$ ; NO reacts catalytically with the ammonia injected and forms  $N_2$  and  $H_2O$ . The AC process has been installed at four power plants in Germany (in two cases downstream of an SDA process). The sulphur content in the fuel used should not exceed 2.3 wt.-%. The  $SO_2$  reduction efficiency is > 95 %, the  $NO_x$  reduction efficiency is > 70 %.

# 3.5.4.2 DESONOX Process/SNOX Process (DESONOX)

The purification of the flue gas by the DESONOX process is based on the simultaneous catalytic reduction of nitrogen oxides ( $NO_x$ ) to nitrogen ( $N_2$ ) and water ( $N_2$ ) and on the catalytic oxidation of sulphur dioxide ( $N_2$ ) to sulphur trioxide ( $N_2$ ). The by-product is sulphuric acid. The process has been installed at one power plant in Germany, where hard coal is used with a sulphur content of about 1 wt.-%. The concentration of catalyst toxics (mainly arsenic, but also chromium, selenium etc.) has to be taken into account. The  $N_2$  reduction efficiency is up to 95 %, the  $N_2$  reduction efficiency is also up to 95 %.

The SNOX process works on the same basic principle as the DESONOX process, with the main difference that reduction and oxidation take place in two separate reaction towers. The SNOX process has been applied at one Danish power plant. No reduction efficiency has been reported yet. The SNOX process is also known as a combination of the Topsøe WSA-2 process and the SCR process.

# 3.5.5 Heavy metals: Secondary measures /12, 20, 21, 22, 23/

Heavy metal emissions are mainly reduced by dust control equipment. Particulate control systems, which are used in coal-fired power plants, are cyclones, wet scrubbers, electrostatic precipitators (ESP), and fabric filters. In most power plants 99 % of the particulates are removed from the flue gases by using ESP or fabric filters. The latter are more efficient in controlling fine particulate matter; wet scrubbers and cyclones are less efficient.

The reduction efficiency of ESP for most elements in the solid state is > 99 %. Only for some higher volatile elements, such as Cd, Pb, Zn and Se, is the reduction efficiency less, but it remains above 90 %. The reduction efficiency of an ESP for Hg depends on the operating temperature of the ESP. A cold-side ESP operating at about 140 °C is estimated to have an average Hg reduction efficiency of about 35 %.

The influence of FGD- and  $DeNO_x$ -units on heavy metal emissions has been investigated mainly in the frame of mass balance studies. WS-FGD-units remove a further fraction of particulate matter in flue gas in addition to dust control. Particle bound elements are removed by FGD-units with an efficiency of about 90 %. In FGD-units, in particular WS-units, the gaseous compounds can additionally condense on particulate matter, which are mainly removed in the prescrubber. With regard to gaseous elements, various studies have shown reduction efficiencies of 30 - 50 % for Hg and 60 - 75 % for Se. Lime contributes over 90 % of the input of As, Cd, Pb and Zn to the FGD.

The abatement of Hg emissions is influenced indirectly by  $DeNO_x$ -units. A high dust SCR-unit improves Hg removal in a subsequent FGD-unit using a lime scrubbing system. The SCR-unit increases the share of ionic mercury (HgCl<sub>2</sub>) to up to 95 %, which can be washed out in the prescrubber of the FGD-unit. A study in the Netherlands found no influence of LNB on heavy metal emissions.

# 3.5.6 Gas turbines /cf. 68, 69/

For gas turbines mainly  $NO_X$  emissions are of most relevance. Primary measures for  $NO_X$  reduction are the following: dry controls (e.g. overstoichiometric combustion in a dry low  $NO_X$  burner with  $\eta = 0.6$  - 0.8, which is a relatively new development as a primary measure) and wet controls (injection of water and/or steam with  $\eta \ge 0.6$  /114/) in order to regulate the combustion temperature. For large gas turbines secondary measures are also installed such as Selective Catalytic Reduction (SCR).

# 3.5.7 Stationary engines /cf. 70/

For spark-ignition engines the main pollutants emitted are  $NO_x$ , CO and unburned hydrocarbons (VOC). For diesel engines sulphur dioxide ( $SO_2$ ) emissions have also to be considered. Emissions of soot also contribute to emissions of heavy metals and persistent organic pollutants, but at this stage insufficient information is available /35/.

Primary measures are installed to optimise combustion conditions (air ratio, reduced load, water injection, exhaust-gas recirculation, optimised combustion chamber etc.). Reduction efficiencies can be given e.g. for exhaust gas recirculation from 6.5 to 12 % and for internal

exhaust gas recirculation from 4 to 37 %. External exhaust gas recirculation (turbo charged models) can have reductions of  $NO_x$  varying from 25 to 34 %. /cf. 114/

Secondary measures are installed, if the emission thresholds cannot be met by adjustments to the engine itself. The following methods are used depending on the air ratio  $\lambda$ :

- $\lambda = 1$  Reduction of NO<sub>X</sub>, CO and VOC by using a three-way catalytic converter (NSCR),
- $\lambda > 1$  Reduction of NO<sub>X</sub> by Selective Catalytic Reduction with NH<sub>3</sub> (SCR), Reduction of other emissions (CO, VOC) using oxidation catalytic converter (NSCR).

Typical conversion rates of  $NO_x$  range from 80 to 95 % with corresponding decreases in CO and VOC. Depending on the system design,  $NO_x$  removal of 80 up to 90 % is achievable. /114/

#### 4 SIMPLER METHODOLOGY

# 4.1 General

# 4.1.1 General / specified emission factors

Here "simpler methodology" refers to the calculation of emissions, based on emission factors and activities. The simpler methodology should only be used in cases where no measured data is available. The simpler methodology covers all relevant pollutants (SO<sub>2</sub>, NO<sub>x</sub>, NMVOC, CH<sub>4</sub>, CO, CO<sub>2</sub>, N<sub>2</sub>O, NH<sub>3</sub>, heavy metals). Special emphasis is put on the pollutants SO<sub>x</sub>, NO<sub>x</sub> and heavy metals, due to the significant contribution of combustion plants as point sources to the total emissions of these pollutants.

A combustion plant can be treated either as a whole (irrespective of kind/size of individual boilers) or on a boiler-by-boiler level. Differences in design and operation of boilers, in fuels used and/or controls installed require different emission factors. The same applies to gas turbines and stationary engines.

The annual emission E is derived from an activity A and a factor which determines their linear relation (see Equation (1)):

$$E_{i} = EF_{i} \cdot A \tag{1}$$

$$\begin{split} E_i & \quad & \text{annual emission of pollutant } i \\ EF_i & \quad & \text{emission factor of pollutant } i \end{split}$$

A activity rate

The activity rate A and the emission factor EF<sub>i</sub> have to be determined on the same level of aggregation by using available data (e.g. fuel consumption) (see Section 6). For the activity rate A, the energy input in [GJ] should be used, but in principle other relations are also applicable.

Two different approaches in order to obtain the emission factor EF<sub>i</sub> are proposed:

# - General emission factor EF<sub>G</sub>

The general emission factor is a mean value for defined categories of boilers taking into account abatement measures (primary and secondary). A general emission factor is only related to the type of fuel used and is applicable for all pollutants considered, except of  $SO_2^5$ . It should only be used where no technique specific data are available (only as a makeshift).

# Specified emission factor EF<sub>R<sub>i</sub></sub>

The specified emission factor is an individually determined value for boilers taking into account abatement measures (primary and secondary). A specified emission factor is related to individual fuel characteristics (e.g. sulphur content of fuel) and to technology specific parameters. The following sections provide determination procedures for suitable specified emission factors for the pollutants  $NO_x$ ,  $SO_x$  and heavy metals.

In principle, plant specific data should be used, if available, for the determination of emission factors. The following Sections 4.1 to 4.8 give recommendations for the estimation and the use of general and specified emission factors as given in Table 4.

**Table 4:** Applicability of general emission factors  $EF_{G_i}$  and specified emission factors  $EF_{R_i}$ 

Pollutant	General emission factor $\mathrm{EF}_{\mathrm{Gi}}$	Specified emission factor $\mathrm{EF}_{R_i}$
$SO_x$	-	+
$NO_x$	+	++1)
Heavy metals	+	++ <sup>2)</sup>
NMVOC, CH <sub>4</sub> , CO, CO <sub>2</sub> , N <sub>2</sub> O, NH <sub>3</sub>	+	*

<sup>+:</sup> possible, but not recommended methodology; ++: possible and recommended methodology;

An accurate determination of full load emissions can only be obtained by using specified emission factors. For the calculation of specified  $SO_x$  and  $NO_x$  emission factors for pulverised coal combustion, a computer programme has been developed (see Annexes 2 - 6 and Annex 14).

If not stated otherwise, the general and specified emission factors presented refer to full load conditions. Start-up emissions have to be considered separately (see Section 4.1.2).

<sup>-:</sup> not appropriate; \*: not available

detailed calculation schemes are given for pulverised coal combustion

detailed calculation schemes are given for coal combustion

<sup>&</sup>lt;sup>5</sup> For the appropriate determination of SO<sub>2</sub> emissions the sulphur content of fuel is required. Therefore, the specified emission factor approach has to be applied.

# 4.1.2 Start-up dependence

Start-up emissions depend on the load design of the plant and on the type of start-up (see Tables 5 and 6). A plant can be designed for:

- peak load: to meet the short-term energy demand,

to meet the energy demand on working days, - middle load:

- base load: continuous operation.

**Table 5:** Load design and start-ups per year

Load design	Start-ups per year		Full load hou	Emission	
	range	value	range	value	relevance <sup>2)</sup>
Peak load <sup>1)</sup>	150 - 500	200	1,000 - 2,500	2,000	x <sup>1)</sup>
Middle load	50 - 250	150	3,000 - 5,000	4,000	xxx
Base load	10 - 20	15	6,000 - 8,000	7,000	X

<sup>1)</sup> For peak load often high-quality fuels (e.g. gas, oil) and often gas turbines are used.

Table 6: Status of the boiler at starting time for a conventional power plant

Type of start-up	Time of stand- still [h] /65/	Status of the boiler	Frequency <sup>2)</sup>	Emission relevance <sup>2)</sup>	
Hot-start	< 8	hot	XXX	X	
Warm-start	8 - ca. 50	warm	XX	XX	
Cold-start	> 50	cold	$\mathbf{x}^{1)}$	XXX	
normally once a year, only for maintenance.					

In order to take into consideration the relevance of start-up emissions, a detailed investigation has been carried out. There, start-up emissions and start-up emission factors have been determined for different types of boilers (DBB, WBB, gas-fired boiler, see Annex 15). Startup emissions are only relevant if secondary measures are installed.

By taking into account boiler characteristics as given in Annex 15, the following general trends of start-up emissions of SO<sub>x</sub>, NO<sub>x</sub> and CO on the type of fuel and type of boiler are obtained (based on /116/).

- For the boilers considered in the detailed investigation it has been found that start-up emissions for the combustion of coal are significantly higher than for the combustion of gas.
- Start-up emissions are higher for dry bottom boilers than for wet bottom boilers and gas boilers.

<sup>2)</sup> x: low; xxx: high.

<sup>&</sup>lt;sup>2)</sup> x: low; xx: medium; xxx: high.

In the following sections, start-up emissions and start-up emission factors derived from measured data are presented as ratios:

$$F^{EF} = EF^{A} / EF^{V}$$
 (2)

F<sup>EF</sup> ratio of start-up and full load emission factors []

EF<sup>A</sup> emission factor at start-up period [g/GJ]

EF<sup>v</sup> emission factor at full load conditions [g/GJ]

$$F^{E} = E^{A} / E^{V}$$
(3)

F<sup>E</sup> ratio of start-up and full load emissions []

E<sup>A</sup> emission during start-up period (see Section 3.2) [Mg]

E<sup>v</sup> emission for full load conditions during start-up period [Mg]

Start-up emissions and full load emissions are related to comparable periods; the energy input (fuel consumption) during the start-up period is lower than during full load operation. The emission factor ratio  $F^{EF}$  is often higher than the emission ratio  $F^{E}$ . Increased specific emissions during the start-up period were found to be compensated to a high degree by the lower fuel consumption. Further pollutant specific results are given in the Sections 4.2 - 4.9.

If start-up emissions are taken into account the corresponding activity rates have to be determined as follows:

$$A = A_{\text{full load}} + A_{\text{cold}} + A_{\text{warm}} + A_{\text{hot}}$$

$$\tag{4a}$$

A activity rate within the period considered [GJ]

 $A_{\text{full load}}$  activity rate for full load operation periods [GJ]

 $A_{cold}$  activity rate for cold start periods [GJ]  $A_{warm}$  activity rate for warm start periods [GJ] activity rate for hot start periods [GJ]

Each sub-activity (e.g.  $A_{cold}$ ) has to be determined separately by totalling the thermal energy input for the respective periods e.g. cold start periods.

Accordingly, Equation (1) becomes:

$$E = EF^{V} \cdot (A_{\text{full load}} + F_{\text{cold}}^{EF} \cdot A_{\text{cold}} + F_{\text{warm}}^{EF} \cdot A_{\text{warm}} + F_{\text{hot}}^{EF} \cdot A_{\text{hot}}) \cdot 10^{-6}$$
(4b)

E emission within the period considered [Mg]

EF<sup>V</sup> emission factor at full load operation conditions [g/GJ]

 $F_{cold/warm/hot}^{EF} \qquad \quad \text{ratio of start-up (cold/warm/hot start) to full load emission factor [\ ]}$ 

A<sub>full load/cold/...</sub> activity rates at full load operation/cold start/... [GJ]

The emission factor at full load conditions  $EF^{V}$  can be approximated by using the emission factors given in Tables 24 and 25 (for  $NO_x$ ) and Table 28 (for CO);  $SO_2$  emission factors can be determined as given in Equation (5). A correction factor for the annual emission can be obtained by calculating the ratio of the annual emissions resulting from Equation (4b) to those determined without consideration of start-up emissions.

# 4.1.3 Load dependence

A load dependence of emissions has only been found for NO<sub>x</sub> emissions released from older types of boiler (see Section 4.3).

# 4.2 SO<sub>2</sub> emission factors

For  $SO_2$ , only specified emission factors  $EF_{R_{SO2}}$  are recommended here. For the determination of specified  $SO_2$  emission factors the following general equation should be used (for emissions of  $SO_3$  see Section 9):

$$EF_{R_{SO2}} = 2 \cdot C_{S_{fuel}} \cdot (1 - \alpha_{s}) \cdot \frac{1}{H_{u}} \cdot 10^{6} \cdot (1 - \eta_{sec} \cdot \beta)$$
(5)

 $EF_{R_{SO2}}$  specified emission factor [g/GJ]

 $C_{S_{\text{fiel}}}$  sulphur content in fuel [kg/kg]

 $\alpha_s$  sulphur retention in ash []

H<sub>u</sub> lower heating value of fuel [MJ/kg]

 $\eta_{sec}$  reduction efficiency of secondary measure []

β availability of secondary measure []

Equation (5) can be used for all fuels, but not all parameters may be of relevance for certain fuels (e.g.  $\alpha_s$  for gas). Default values for reduction efficiencies and availabilities of secondary measures installed are presented in Table 7. The technologies listed in Table 7 are mainly installed in the case of coal-fired boilers, but they can also be applied when burning other fuels.

**Table 7:** Default values for secondary measures for SO<sub>2</sub> reduction (all fuels) /18, 19/

No.	Type of secondary measure	Reduction efficiency $\eta_{sec}$ [ ]	Availability β[]
1	WS	0.90	0.99
2	SDA	0.90	0.99
3	DSI	0.45	0.98
4	LIFAC	0.70	0.98
5	WL	0.97	0.99
6	WAP	0.88	0.99
7	AC	0.95	0.99
8	DESONOX	0.95	0.99

# 4.2.1 Combustion of coal

SO<sub>2</sub> emission factors for coal fired boilers can be calculated by using Equation (5). If some input data are not available, provided default values based on literature data can be used:

- C <sub>s,fuel</sub>	see Annexes 7 and 8, Table 23,
- $\alpha_{\rm s}$	see Table 8,
- $\eta_{sec}$ and $\beta$	see Table 7,
- H <sub>u</sub>	see Annexes 7 and 8.

For further details concerning the calculation of SO<sub>2</sub> emission factors, see Annexes 2 (flowsheet of the computer programme) and 3 (description of the computer programme). Default values for sulphur retention in ash for coal fired boilers are presented in Table 8.

**Table 8:** Default values for the sulphur retention in ash  $(\alpha_s)$  for pulverised coal fired boilers

Type of boiler	$\alpha_{s}[]$		
	Hard coal	Brown coal	
DBB	0.05	$0.3^{1)}$	
WBB	0.01	-	

<sup>1)</sup> average value; in practice, a range of 0.05 - 0.60 can occur (e.g. in the Czech Republic 0.05 is used)

Emission factors obtained by using Equation (5) are related to full load conditions; start-up emissions are not taken into account. If a flue gas desulphurisation unit is installed, start-up emissions should be considered as given in Section 4.1.2. The relevance of start-up emissions of SO<sub>2</sub> depends strongly on the following parameters:

- the type of fuel (e.g. SO<sub>x</sub> emissions are directly related to the fuel sulphur content),
- the status of the boiler at starting time (hot, warm or cold start, see also Table 6),
- start-up of the flue gas desulphurisation unit (FGD direct or in by-pass configuration),
- limit for  $SO_x$  emissions, which has to be met (boiler specific limits can be set up below the demands of the LCP Directive).

For the combustion of coal in dry bottom boilers, the following ranges and values of F<sup>EF</sup>, F<sup>E</sup> have been obtained within the investigation outlined in Annex 15:

**Table 9:** Ratios of start-up to full load emission factors  $F^{EF}$  and ratios of start-up to full load emissions  $F^{E}$  for  $SO_{2}$  for dry bottom boilers

	Ratio of start-up to full load emission factors F <sup>EF</sup> [ ]	Ratio of start-up to full load emissions F <sup>E</sup> [ ]
Range	3 - max. 16	1 - max. 4
Values for direct start-up of the FGD	F <sub>cold</sub> : 5 F <sub>warm</sub> : 5	$egin{array}{c} F^{E}_{ m cold} \colon & 1 \ & F^{E}_{ m warm} \colon & 1 \end{array}$
	$F_{\text{hot}}^{\text{EF}}$ : 4	$F_{\text{hot}}^{\text{E}}: 1$

	Ratio of start-up to full load emission factors F <sup>EF</sup> [ ]	Ratio of start-up to full load emissions F <sup>E</sup> [ ]
Range	3 - max. 16	1 - max. 4
Values for by-pass start-up of the FGD	F <sub>cold</sub> : 8.5 - 16 F <sub>warm</sub> : 5 - 14.5	$F_{\text{cold}}^{\text{E}}$ : 2 - 4.5 $F_{\text{warm}}^{\text{E}}$ : 1 - 3.5
	$F_{hot}^{EF}$ : 5 - 5.5	$F_{\text{hot}}^{\text{E}}$ : 1.5

 $F_{\text{cold,warm,hot}}^{\text{EF}}$  Ratio of start-up to full load emission factors for cold, warm or hot start-ups (see also Table 6)

 $F_{\text{cold,warm,hot}}^{\text{E}}$  Ratio of start-up to full load emissions for cold, warm or hot start-ups (see also Table 6)

The values from the direct start-up of the FGD show, that start-up emissions of  $SO_2$  are not relevant (ratio  $F^E$  of ca. 1). In the case of a by-pass start-up of the FGD, start-up emissions of  $SO_2$  are significant for hot, warm and cold starts; start-up emissions can be up to 4 times higher than emissions in a comparable full load time span (based on /116/).

# 4.2.2 Combustion of other fuels (biomass, waste, liquid fuels, gaseous fuels)

 $SO_2$  emissions are directly related to the sulphur content of biomass, waste, liquid and gaseous fuels (see Equation (5)). The sulphur retention in ash  $\alpha_s$  is not relevant. The reduction efficiency  $\eta_{sec}$  and the availability  $\beta$  of installed secondary measures have to be taken into account (in particular for the combustion of waste). Default values for  $\eta$  and  $\beta$  are given in Table 7. Sulphur contents of different fuels are given in Table 23 and in Annexes 7 and 8.

# 4.3 $NO_x$ emission factors

For the determination of  $NO_x$  emissions, general as well as specified  $NO_x$  emission factors can be used. Emission factors are listed in Tables 24 and 25 depending on installed capacity, type of boiler, primary measures and type of fuel used.

# 4.3.1 Combustion of pulverised coal

Specified  $NO_x$  emission factors can be calculated individually for pulverised coal fired boilers. Due to the complex reaction mechanism of  $NO_x$  formation (see also Section 3.4) an estimate of specified  $NO_x$  emission factors can only be made on the basis of empirical relations as given in Equation (6). The decisive step in Equation (6) is the undisturbed  $NO_x$  formation (without primary measures) inside the boiler  $(C_{NO_{2boiler}})$ .  $C_{NO_{2boiler}}$  is determined by an empirical equation depending on fuel parameters only, as described in Annex 5.

$$EF_{R_{NO_2}} = C_{NO_2, boiler} \cdot (1 - \eta_{prim}) \cdot \frac{1}{H_{in}} \cdot 10^6 \cdot (1 - \eta_{sec} \beta)$$
 (6)

**Table 11:** Default values for reduction efficiency and availability of secondary measures for  $NO_x$  reduction /18, 19/ (all fuels)

Emission factors of NO<sub>2</sub> for different coal compositions have been calculated by using default values as given above and are listed in Table 25.

The load dependence of  $NO_X$  emissions can be split into two different phenomena (see Sections 4.1.2 and 4.1.3):

# a) Load variations during normal operation:

Load variations are discussed very controversially in the literature. Often a strong correlation of  $NO_X$  emissions and load is reported. Load corrections, e.g. as given in /66/, may be appropriate for older types of boilers.

For boilers of modern design, with optimised combustion conditions e.g. by primary measures, only a negligible load dependence has been reported /64/. This is explained by the fact that for modern boilers (with primary measures) under reduced load conditions an overstoichiometric air ratio is applied in order to achieve an acceptable burning out of the fuel, which leads to  $NO_x$  emission factors similar to those obtained under full load conditions. Therefore, for boilers of modern design no load correction is proposed.

For older boilers (without primary measures) a load dependent emission factor can be calculated according to Equation (7), which has been derived for German dry bottom boilers (combustion of hard coal) /71/:

$$EF = 1,147 + 0.47 \cdot L \tag{7}$$

EF emission factor [g/MWh]<sup>7</sup>
L actual load [MW]

At this stage, no general approach is available for estimating the load dependence of  $NO_x$  emissions. However, a load correction factor can be obtained by using a ratio between reduced load and full load emission factors:

 $<sup>^{7}</sup>$  1 MWh = 3.6 GJ

$$k^{\text{load}} = \frac{EF^{\text{Reduced load}}}{EF^{\text{V}}} = \frac{1,147 + 0.47 \cdot L}{1,147 + 0.47 \cdot L_{\text{no min al}}}$$
(8)

 $\begin{array}{ll} k^{load} & \text{ratio of reduced load to full load emission factor [ ]} \\ EF^{Reduced \, load} & \text{emission factor for reduced load conditions [g/MWh]}^6 \\ EF^{V} & \text{emission factor for full load conditions [g/MWh]}^6 \\ \end{array}$ 

 $\begin{array}{ll} L & \text{actual load [MW]} \\ L_{\text{nominal}} & \text{nominal load [MW]} \end{array}$ 

Figure 1.1 gives a graphic presentation of the results of Equation (8):

**Figure 1.1:** Variation of k<sup>load</sup> with load

If reduced load operation is taken into account the corresponding activity rates have to be determined as follows:

$$A = A_{\text{full load}} + A_{\text{load } 1} + A_{\text{load } 2} + \dots$$

$$(9a)$$

 $\begin{array}{ll} A & \text{activity rate within the period considered [GJ]} \\ A_{\text{full load}} & \text{activity rate for full load operation periods [GJ]} \\ \end{array}$ 

A load i activity rate for reduced load operation periods at level i [GJ]

Each sub-activity (e.g.  $A_{load\ 1}$ ) has to be determined separately by totalling the thermal energy input for the respective periods of operation e.g. at load level 1.

Emissions are calculated according to Equation (9b):

$$E = EF^{V} \cdot (A_{\text{full load}} + k^{\text{load 1}} \cdot A_{\text{load 1}} + k^{\text{load 2}} \cdot A_{\text{load 2}} + \dots) \cdot 10^{-6}$$
(9b)

E emission within the period considered [Mg] EF<sup>V</sup> emission factor at full load conditions [g/GJ]

A<sub>load i</sub> activity rates at load level i [GJ]

k<sup>load i</sup> ratio of reduced load to full load emission factor at load level i []

If secondary measures are installed, no load correction for  $NO_X$  emissions has to be taken into account.

# b) Load variations with respect to start-up behaviour:

Emission factors for  $NO_x$ , as given in Tables 24 and 25, are related to full load conditions; start-up emissions are not taken into account. If an SCR is installed, start-up emissions should be considered as given in Section 4.1.2. The relevance of start-up emissions of  $NO_x$  depends strongly on the following parameters:

- the type of boiler (e.g. NO<sub>x</sub> emissions released by wet bottom boilers are always higher than those by dry bottom boilers, due to higher combustion temperatures),
- the type of fuel used (e.g. fuel nitrogen also contributes to the formation of NO<sub>x</sub>),
- the status of the boiler at starting time (hot, warm or cold start),
- the specifications of any individual start-up, such as
  - -- the duration and the velocity of start-up,
  - -- the load level (reduced load or full load),
  - -- the configuration of secondary measures (e.g. the start-up time of the high-dust-configurations (SCR-precipitator-FGD) depends on the boiler load, due to the fact that the SCR catalyst is directly heated by the flue gas; tail-end-configurations (precipitator-FGD-SCR) can have shorter start-up times, due to the fact that the SCR catalyst can be preheated by an additional furnace),
  - -- emission standards, which have to be met (boiler-specific emission standards can be set up below the demands of the LCP Directive).

In the investigation mentioned in Annex 15 the measured data from different boilers have been analysed. For the combustion of coal the following ratios have been obtained (based on /116/):

- For the combustion of coal in dry bottom boilers the following ranges and values can be given:

	Ratio of start-up to full load emissions factors F <sup>EF</sup> []	Ratio of start-up to full load emissions F <sup>E</sup> []
Range	2 - max. 6	1 - 2
Values for DBB	$F_{cold}^{EF}$ : 3.5 – 6 $F_{warm}^{EF}$ : 3 – 6.5 $F_{hot}^{EF}$ : 2.5 – 3	$F_{cold}^{E} : 1.5 - 2$ $F_{warm}^{E} : 1 - 2$ $F_{hot}^{E} : 1 - 1.5$

**Table 12:** Ratios of start-up to full load emission factors F<sup>EF</sup> and ratios of start-up to full load emissions F<sup>E</sup> for NO<sub>2</sub> for dry bottom boilers

 $F_{\text{cold,warm,hot}}^{\text{EF}} \quad \text{Ratio of start-up to full load emission factors for cold, warm or hot start-ups (see also Table 6)}$ 

 $F^{E}_{cold,warm,hot} \quad \text{Ratio of start-up to full load emissions for cold, warm or hot start-ups (see also Table 6)}$ 

The investigation revealed that start-up emissions of NO<sub>2</sub> were mostly higher than emissions under full load conditions. There is a dependence between start-up emissions (see Section 3.2) and the time of standstill of the boiler: cold starts showed emissions about 2 times higher, warm starts about 1 up to 2 times higher and hot starts about 1 up to 1.5 higher than at full load conditions. Start-up emission factors can be up to 6 times higher than full load emission factors. At the investigated boilers the SCR was installed in a high-dust configuration.

- For the combustion of coal in wet bottom boilers (SCR in tail-end configuration) it was found that start-up emissions were not higher than full load emissions (ratio of ≤1). However, this consideration is based on data of only two boilers. Measured data for hot starts was not available.

NO<sub>x</sub> emissions, in particular for the combustion of coal in DBB, might be underestimated, if these effects are not taken into account.

# 4.3.2 Combustion of other fuels (biomass, waste, liquid fuels, gaseous fuels)

The emission calculation is based on Equation (1). During the combustion of solid and liquid fuels, fuel-NO and thermal-NO are formed. For gaseous fuels only thermal-NO $_x$  is relevant, as gaseous fuels do not contain any fuel-nitrogen. For gaseous fuels the emission reduction is mainly achieved by primary measures. There are several biomass-fuelled plants with SNCR in Sweden.

The analysis of emission data from a gas fired boiler, equipped with an SCR, revealed that start-up emissions are not of relevance (ratios  $F^E$  were below 1) (based on /116/).

# 4.4 NMVOC/CH<sub>4</sub> emission factors

The emission calculation is based on Equation (1). Fuel and technique specific emission factors are given in Tables 26 and 27.

# 4.5 CO emission factors

The emission calculation is based on Equation (1). Fuel and technique specific emission factors are given in Table 28 (full load conditions); start-up emissions are not taken into account. CO emissions at starting time and under full load conditions are mainly influenced by the combustion conditions (oxygen availability, oil spraying etc.). In the detailed investigation start-up emissions for CO have only been found to be relevant for the combustion of coal. Start-up emissions for CO are determined for the time when burners switch-on up to the time when the boiler operates on minimum load.

For the combustion of coal and gas the following results have been obtained (based on /116/ see also Section 4.1.2):

- For the combustion of coal in dry bottom boilers the following ranges can be given:

**Table 13:** Ratios of start-up to full load emission factors  $F^{EF}$  and ratios of start-up to full load emissions  $F^{E}$  for CO for dry bottom boilers

	Ratios for start-up to full load emission factors F <sup>EF</sup> [ ]	Ratios for start-up to full load emissions F <sup>E</sup> [ ]
Range	0.5 - 3.5	0.1 - 0.7
Values for DBB	$F_{\text{cold}}^{\text{EF}} : 1.5 - 3.5$ $F_{\text{warm}}^{\text{EF}} : 1$ $F_{\text{hot}}^{\text{EF}} : 0.5$	$F_{cold}^{E} : 0.4 - 0.7$ $F_{warm}^{E} : 0.2 - 0.7$ $F_{hot}^{E} : 0.1$

 $F_{\text{cold,warm,hot}}^{\text{EF}}$  Ratio of start-up to full load emission factors for cold, warm or hot start-ups (see also Table 6)

 $F_{\text{cold warm hot}}^{\text{E}}$  Ratio of start-up to full load emissions for cold, warm or hot start-ups (see also Table 6)

The values in Table 13 show that start-up emissions for CO for DBB are lower than full load emissions for the boilers considered.

- Start-up emissions from wet bottom boilers can be up to 1.2 times higher than full load emissions for cold starts ( $F^{EF} = 4$ ); they are lower for warm starts ( $F^{E} = 0.3$ ;  $F^{EF} = 0.8$ ).
- Start-up emissions of CO from gas boilers are also negligible.

# 4.6 CO<sub>2</sub> emission factors

The emission calculation is based on Equation (1). Fuel specific emission factors are given in Table 29. For the determination of specified  $CO_2$  emission factors, the following general Equation (10) can be used:

$$EF_{R_{CO2}} = \frac{44}{12} \cdot C_{C_{fuel}} \cdot \varepsilon \cdot \frac{1}{H_{u}} \cdot 10^{6}$$

$$\tag{10}$$

EF<sub>RCO2</sub> specified emission factor [g/GJ]

 $C_{C_{fuel}}$  carbon content of fuel (in mass C/mass fuel [kg/kg])

 $\epsilon \qquad \qquad \text{fraction of carbon oxidised [ ]} \\ H_u \qquad \qquad \text{lower heating value of fuel [MJ/kg]}$ 

Default values for carbon content and lower heating value of different coals, available on the world market, are given in Annexes 7 and 8. The fraction of carbon oxidised ( $\epsilon$ ) is defined as the main part of carbon which is oxidised to CO<sub>2</sub>; small amounts of carbon may remain unoxidised. Default values for  $\epsilon$  according to IPCC /61/ are for liquid fuels 0.99, for solid fuels 0.98 and for gaseous fuels 0.995. In this approach it is assumed that the only product of the oxidation is CO<sub>2</sub>. Nevertheless, double counting of CO<sub>2</sub> has to be avoided: products of incomplete oxidation, like CO, must not be converted into CO<sub>2</sub>.

The IPCC/OECD presented an overall model (the so-called reference approach) specially designed for the calculation of  $CO_2$  emissions on a national level (not on a plant level) /61/. This methodology is based on national energy balances.

# 4.7 $N_2O$ emission factors

The emission calculation is based on Equation (1). The fuel and technique specific emission factors are given in Table 30. At this stage, several pilot studies using measured data are described in the literature /13, 14, 25, 26, 27/. A complete list of influencing parameters has not yet been identified.

# 4.8 NH<sub>3</sub> emission factors

Emission factors referring to the energy input are not yet available. The available data for ammonia slip at SCR/SNCR installations are based on measurements and are related to the flue gas volume: SCR/SNCR installations are often designed for an ammonia slip of about 5 ppm (3.8 mg NH<sub>3</sub>/m<sup>3</sup> flue gas) /45, 62/. The ammonia slip at SCR and SNCR installations increases with an increasing NH<sub>3</sub>/NO<sub>x</sub> ratio, but also with a decreasing catalyst activity.

# 4.9 Heavy metal emission factors

For heavy metals, general and specified emission factors can be used. Emission factors, depending on the fuel used and the technique installed, are given in Table 31.

The IPCC/OECD presented an overall model (the so-called reference approach) specially designed for the calculation of  $CO_2$  emissions on a national level (not on a plant level) /61/. This methodology is based on national energy balances.

# 4.9.1 Combustion of coal

For an individual determination of specific heavy metal emission factors, three different methodologies can be applied, taking into account:

- fuel composition (particle-bound and gaseous emissions),

- fly ash composition (particle-bound emissions),

- fly ash concentration in clean gas (particle-bound emissions).

The choice of the methodology depends on data availability.

# 4.9.1.1 Calculation of specified emission factors based on fuel composition /cf. 35/

Emissions of heavy metals associated with particulate matter and gaseous emissions are assessed subsequently as given in Equation (11). The enrichment behaviour of heavy metals with regard to fine particles is taken into account as an enrichment factor (see also Section 3.4). Gaseous emissions have to be taken into account additionally in the case of arsenic, mercury and selenium.

$$EF_{R_{HM}} = C_{HM_{coal}} \cdot f_a \cdot f_e \cdot 10^{-2} \cdot (1 - \eta_p) + C_{HM_{coal}} \cdot f_g \cdot 10^{-2} \cdot (1 - \eta_g)$$
(11)

 $EF_{R_{\rm HM}} \hspace{0.5cm} \text{specified emission factor of heavy metal (in mass pollutant/mass coal [g/Mg])} \\$ 

 $C_{HM_{coal}}$  concentration of heavy metal in coal [mg/kg]

 $f_a$  fraction of ash leaving the combustion chamber as particulate matter [wt.-%]

f<sub>e</sub> enrichment factor []

f<sub>g</sub> fraction of heavy metal emitted in gaseous form [wt.-%]

 $\eta_p$  efficiency of the dust control equipment []

 $\eta_g$  efficiency of the emission control equipment with regard to gaseous heavy metals []

The characteristics of fuel and technology are taken into account by  $f_a$  and  $f_e$  and the following default values are proposed:

**Table 14:** Default values for f<sub>a</sub> for different combustion technologies (based on /35/)

Type of boiler	f <sub>a</sub> [wt%]
DBB (Pulverised coal)	80
Grate firing	50
Fluidised bed	15

Heavy metal	f <sub>e</sub> [ ]		
	range	value <sup>1)</sup>	
Arsenic	4.5 - 7.5	5.5

Nickel	1.5 - 5	3.3	
Lead	4 - 10	6	

**Table 15:** Default values for  $f_e$  for different heavy metals released by the combustion of coal (based on /35/)

Gaseous emissions (arsenic, mercury and selenium) are calculated from the heavy metal content in coal; the fraction emitted in gaseous form is given in Table 16. The efficiency of emission control devices with regard to these elements is outlined in Section 3.5.5.

Selenium

**Table 16:** Fractions of heavy metals emitted in gaseous form  $(f_g)$  released by the combustion of coal /35/

Heavy metal	f <sub>g</sub> [wt%]	
Arsenic	0.5	
Mercury	90	
Selenium	15	

4.9.1.2 Calculation of specified emission factors based on fly ash composition /cf. 39/ If the concentration of heavy metals in raw gas fly ash is known, emission factors of heavy metals can be assessed by Equation (12). Gaseous emissions have to be taken into account separately as outlined in Section 4.9.1.1.

$$EF_{R_{HM,p}} = EF_f \cdot C_{HM_{FA,raw}} \cdot 10^{-3} \cdot (1 - \eta_p)$$
 (12)

 $EF_{R_{HMP}} \quad \text{specified emission factor of heavy metal in particulate matter (in mass pollutant/mass coal [g/Mg])}$ 

EF<sub>f</sub> fly ash emission factor of raw gas (in mass particulate matter/mass coal [kg/Mg])

 $C_{HM_{FA,\text{\tiny FA,PBW}}} \ \ \text{heavy metal concentration in raw gas fly ash (in mass pollutant/mass particulate matter [g/Mg])}$ 

 $\eta_p$  efficiency of dust control equipment []

Zinc 5 - 9 7

Recommended value, if no other information is available.

Values of  $EF_f$  can be calculated in a technology specific way using default parameters, as given in Table 17 depending on the content of ash in coal (a) in [wt.-%].

**Table 17:** Fly ash emission factor for raw gas (EF<sub>f</sub>) as function of the ash content in coal (a) [wt.-%] /cf. 39/

	$\mathrm{EF_{f}}$
Technology	(in mass particulate matter / mass coal)
	[kg/Mg]
Cyclone	1.4·a
Stoker	5.9·a
Pulverised coal combustion	7.3·a

The emission factors calculated by taking into account the fuel or the fly ash composition mainly depend on the estimation of the efficiency of dust control equipment.

4.9.1.3 Calculation of specified emission factors based on fly ash concentration in clean flue gas /cf. 36/

If the concentration of heavy metals in fly ash in clean flue gas is known, emission factors of heavy metals can be assessed by Equation (13). Gaseous emissions have to be taken into account separately, as outlined in Section 4.9.1.1.

$$EF_{R_{HM,P}} = C_{HM_{FA,clean}} \cdot C_{FG} \cdot V_{FG} \cdot 10^{-9}$$

$$\tag{13}$$

 $EF_{R_{HM,P}}$  specified emission factor of heavy metal in particulate matter (in mass pollutant/mass coal [g/Mg])

 $C_{HM_{FA,clean}}$  concentration of heavy metal in fly ash in clean flue gas (in mass pollutant/mass fly ash [g/Mg])

C<sub>FG</sub> concentration of fly ash in clean flue gas (in mass fly ash/volume flue gas [mg/m³])
V<sub>FG</sub> specific flue gas volume (in volume flue gas/ mass coal [m³/Mg])

Fuel and technology specific heavy metal concentrations in fly ash in clean flue gas ( $C_{HM_{FA,clean}}$ ) are given in Table 18 /36/:

n. a.: not available

# 4.9.2 Combustion of other fuels

General emission factors for oil and gas combustion can be found in Table 31. Among the other fuels, only waste is relevant for heavy metal emissions. Emission factors for the combustion of waste are currently not available (reported emission factors within the literature mainly refer to the incineration of waste).

# 5 DETAILED METHODOLOGY

The detailed methodology refers to the handling of measured data in order to determine annual emissions or in order to verify emission factors (for comparison purposes). Annual emissions from major contributors should only be obtained by using continuously measured data which are normally available if secondary abatement technologies are installed. Furthermore, the detailed methodology should be used whenever measured data are available; e.g. for medium and small sized combustion installations periodically measured data are often available.

Measurements are carried out downstream of the boiler or at the stack; measured values obtained by both variants are usable.

National monitoring programmes should include guidelines for quality assurance of measurements (measuring places, methods, reporting procedures, etc.).

The pollutants normally measured at power plants are  $SO_2$ ,  $NO_x$ , CO, and particulate matter. Gaseous emissions of  $SO_2$ ,  $NO_x$ , and CO are treated in Section 5.1. Continuously measured particulate matter emission data can be used to estimate heavy metal emissions (see Section 5.2).

# 5.1 Gaseous emissions

It is desirable to obtain annual emissions in [Mg]. The annual emission as a function of time is normally given by the following Equation (14):

$$E = \int_{T} e(t) \qquad dt \tag{14}$$

- E emission within the period T [Mg]
- e (t) emission per unit of time in the periods of operation [Mg/h]
- t time [h]
- T annual time period (see also Figure 1)

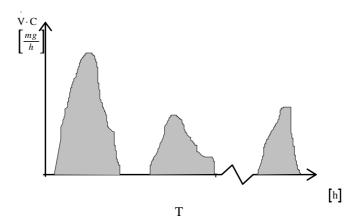

Usually, the emission e(t) cannot be or is not directly measured. Therefore, for practical reasons, the concentration of pollutants and the flue gas volume are used for the determination of e(t), as described by Equation (15):

$$e(t) = V(t) \cdot C(t) \tag{15}$$

- e (t) emission in the periods of operation [Mg/h]
- V(t) flue gas volume flow rate [m<sup>3</sup>/h]

C (t) flue gas concentration of a pollutant [mg/m³] Usually, emission fluctuations occur within a year (see Figure 1) as:

- periodical fluctuations (e.g. daily, weekly, seasonally), due to load management depending on the demand of e.g. district heat or electricity,
- operational fluctuations (e.g. start-ups/shut downs, raw material properties, working conditions/reaction conditions).

V flue gas volume flow rate [m<sup>3</sup>/h]

C flue gas concentration of a pollutant (abatement techniques installed are included) [mg/m<sup>3</sup>]

t time [h]

 $t_{bn}$  beginning of operation (e.g. start-up of boiler) [h]  $t_{en}$  ending of operation (e.g. shut down of boiler) [h]

T annual time period

Figure 1: Periods of operation of a combustion installation

The following approaches can be used to determine annual emissions depending on the level of detail of measured data available.

## - First approach:

The flue gas volume and the concentration of a pollutant are measured continuously (e.g. in Finland). Then, the annual emission is given exactly by the following Equation (16):

$$E = 10^{-9} \int_{T} V(t) \cdot C(t) dt \tag{16}$$

E emission within the period T [Mg]

V(t) flue gas volume flow rate [m<sup>3</sup>/h]

C (t) flue gas concentration of a pollutant (abatement techniques installed are included) [mg/m³]

t time [h]

T annual time period (see also Figure 1)

The precision of measurements of V(t) and C(t) depends on the performance of the analytical methods (e.g. state-of-the-art) used. In particular, the regular calibration of measuring instruments is very important. Analytical methods commonly used for  $NO_x$  detect only NO

and those used for  $SO_x$  detect only  $SO_2$ . It is implicitly assumed that  $NO_2$  in the flue gas is normally below 5 %, and that  $SO_3$  in the flue gas is negligible. Nevertheless, for some combustion plants the amounts of  $NO_2$  and/or  $SO_3$  formed can be significant and have to be detected by appropriate analytical methods. The measured values have to be specified with regard to dry/wet flue gas conditions and standard oxygen concentrations<sup>8</sup>.

For the annual time period T considered, a case distinction has to be made:

- calendar year  $T_1$  (e.g. including time out of operation),
- real operating time T<sub>2</sub> of boiler/plant (e.g. start-ups are reported when "burner on/off"),
- official reporting time T<sub>3</sub> determined by legislation (e.g. start-ups are reported, as soon as the oxygen content in the flue gas goes below 16 %),

where  $T_3 \subset T_2 \subset T_1$ . If C(t) is only available for  $T_3$ , adequate corrections have to be provided.

## Second approach:

Due to the difficulty in measuring V(t) continuously in large diameter stacks, in most cases the flue gas volume flow rate V(t) is not measured. Then the annual emission can be determined by Equation (17):

$$E = 10^{-9} \dot{\vec{V}} \int_{T} C(t)dt \tag{17}$$

E emission within the period T [Mg]

 $\vec{\dot{V}}$  average flue gas volume flow rate [m<sup>3</sup>/h]

C(t) flue gas concentration of a pollutant (abatement techniques installed are included) [mg/m³]

t time [h]

T annual time period (see also Figure 1)

The average flue gas volume flow rate  $\overline{V}$  (dry conditions) can be determined according to the following Equations (18) and (19):

$$\overline{\dot{V}} = V_{FG} \cdot \dot{m}_{fuel} \tag{18}$$

 $\overline{\dot{V}}$  average flue gas volume flow rate [m<sup>3</sup>/h]

V<sub>FG</sub> dry flue gas volume per mass fuel [m<sup>3</sup>/kg]

 $\dot{m}_{fuel}$  fuel consumption rate [kg/h]

$$V_{FG} \approx 1.852 \left[ \frac{m^3}{kg} \right] \cdot C_c + 0.682 \left[ \frac{m^3}{kg} \right] \cdot C_s + 0.800 \left[ \frac{m^3}{kg} \right] \cdot C_N + V_{N_{air}}$$
 (19)

V<sub>FG</sub> dry flue gas volume per mass fuel [m<sup>3</sup>/kg]

C<sub>c</sub> concentration of carbon in fuel [kg/kg]

C<sub>s</sub> concentration of sulphur in fuel [kg/kg]

<sup>&</sup>lt;sup>8</sup> In some countries the measured values obtained are automatically converted into values under standard oxygen concentrations (e.g. in Germany).

C<sub>N</sub> concentration of nitrogen in fuel [kg/kg]

 $V_{N_{air}}$  specific volume of air nitrogen (in volume/mass fuel [m<sup>3</sup>/kg])

This calculation of V according to Equation (19) can be performed by the computer programme (see Annex 6) by using default values for  $C_C$ ,  $C_S$ ,  $C_N$  and  $V_N$ .

# - Third approach:

In some countries the term  $\int_T C(t)dt$  is available as an annual density function P(C)

(histogram). In this case Equation (17) can be simplified to:

$$E = \overline{\dot{V}} \cdot \overline{C} \cdot t_{op} \cdot 10^{-9} \tag{20}$$

where 
$$\overline{C} = \int_{0}^{\infty} P(C) \cdot C \cdot dC$$
 (21)

E emission within the period T [Mg]

 $\overline{\dot{V}}$  average flue gas volume flow rate [m<sup>3</sup>/h]

 $\overline{C}$  expected value (mean value) of the flue gas concentration for each pollutant (abatement techniques installed are included) [mg/m<sup>3</sup>]

t<sub>op</sub> annual operating time [h]

P(C) density function []

C flue gas concentration per pollutant as given in the histogram [mg/m<sup>3</sup>]

The variable  $t_{op}$  has to be introduced consistently with  $\overline{V}$  and  $\overline{C}$  according to periods  $T_1$ ,  $T_2$  or  $T_3$  mentioned above. If e.g. start-ups are not included, they should be taken into account as given in Sections 4.1, 4.2 and 4.4.

## - Fourth approach:

If neither  $T_2$  nor  $T_3$  are available, the annual full load operating hours can also be used. Then Equation (20) becomes:

$$E = \overline{\dot{V}}_{normed} \cdot \overline{C} \cdot t_{on}^{full \, load} \cdot 10^{-9}$$
(22)

E emission within the period considered [Mg]

 $\dot{V}_{\it normed}$  average flue gas volume flow rate related to full load operation [m³/h]

 $\overline{C}$  mean value of the flue gas concentration for each pollutant (abatement techniques installed are included) [mg/m<sup>3</sup>]

 $t_{op}^{\text{full load}}$  annual operating time expressed as full load operating hours [h]

From here, emission factors, based on measured values, can be derived e.g. for verification purposes:

$$EF = \frac{E}{A} \cdot 10^6 \tag{23}$$

EF emission factor [g/GJ]

E emission within the period considered [Mg]

A activity rate within the time period considered [GJ]

## 5.2 Heavy metal emissions

Continuously measured values for the total heavy metal emissions (particle-bound and gaseous) are not available for the combustion of fossil fuels. National legislation can require periodical measurements, e.g. weekly measurements of heavy metal emissions [mg/m³] in the case of waste incineration/combustion.

The emissions of particle-bound heavy metals depend on the emission of particulate matter which is normally periodically or continuously monitored. Therefore, the particle-bound heavy metal emissions can be derived from the element content in particulate matter. The heavy metal emission factor can be back-calculated as follows:

$$EF = \frac{\overline{\dot{m}}_{FA} \cdot \overline{C}_{HM_{FA.clean}}}{A} \tag{24}$$

EF emission factor [g/GJ]

 $\dot{m}_{FA}$  mass of fly ash within the period considered [Mg]

 $\overline{C}_{HM_{FAclean}} \ \ \text{average concentration of heavy metal in fly ash (in mass pollutant/mass fly ash [g/Mg])}$ 

A activity rate within the period considered [GJ]

Measured data should also be used to replace the default values of Equation (13) for  $C_{\text{HM}_{\text{FAclean}}}$  and  $C_{\text{FG}}$ .

#### 6 RELEVANT ACTIVITY STATISTICS

In general, the published statistics do not include point sources individually. Information on this level should be obtained directly from each plant operator.

On a national level, statistics can be used for the determination of fuel consumption, installed capacity and/or types of boilers mainly used. The following statistical publications can be recommended:

- Office for Official Publication of the European Communities (ed.): Annual Statistics 1990;
   Luxembourg 1992
- Commission of the European Communities (ed.): Energy in Europe Annual Energy Review: Brussels 1991
- Statistical Office of the European Communities (EUROSTAT) (ed.): CRONOS Databank,
   1993
- OECD (ed.): Environmental Data, Données OCDE sur l'environnement; compendium 1993
- Commission of the European Communities (ed.): Energy in Europe; 1993 Annual Energy Review; Special Issue; Brussels 1994

 EUROSTAT (ed.): Panorama of EU Industry'94; Office for official publications of the European Communities; Luxembourg 1994

#### 7 POINT SOURCE CRITERIA

Point source criteria for a combustion plant according to CORINAIR are given in chapter AINT and in /41/.

# 8 EMISSION FACTORS, QUALITY CODES AND REFERENCES

Tables 23 - 31 list emission factors for all pollutants considered, except for SO<sub>2</sub>. For SO<sub>2</sub> emission factors have to be calculated individually (see Equation (5)). Sulphur contents of different fuels are given. The emission factors have been derived from the literature, from the calculations presented here (see also Section 4) and from recommendations from expert panel members. All emission factor tables have been designed in a homogenous structure: Table 20 contains the allocation of SNAP activities used related to combustion installations, where three classes are distinguished according to the thermal capacity installed. Table 21 includes the main types of fuel used within the CORINAIR90 inventory. Table 22 provides a split of combustion techniques (types of boilers, etc.); this standard table has been used for all pollutants. The sequence of the emission factor tables is:

- Table 20: SNAP code and SNAP activity related to the thermal capacities installed in combustion plants
- Table 21: Selection of relevant fuels from NAPFUE and lower heating values for boilers, gas turbines and stationary engines
- Table 22: Standard table for emission factors for the relevant pollutants
- Table 23: S-contents of selected fuels
- Table 24: NO<sub>x</sub> emission factors [g/GJ] for combustion plants
- Table 25:  $NO_X$  emission factors [g/GJ] for coal combustion according to the model description (see Annexes 4 and 5)
- Table 26: NMVOC emission factors [g/GJ] for combustion plants (coal combustion)
- Table 27: CH<sub>4</sub> emission factors [g/GJ] for combustion plants
- Table 28: CO emission factors [g/GJ] for combustion plants
- Table 29: CO<sub>2</sub> emission factors [kg/GJ] for combustion plants
- Table 30: N<sub>2</sub>O emission factors [g/GJ] for combustion plants
- Table 31: Heavy metal emission factors [g/Mg] for combustion plants

References of the emission factors listed are given in footnotes of the following tables. Quality codes are not available in the literature.

- A principal differentiation between coking coal and steam coal is given in section 3.2. Further differentiation between coking coal and steam coal can be made by using the content of volatiles: coking coal contains 20 30 wt.-% volatiles (maf), steam coal contains 9.5 20 wt.-% volatiles (maf) (based on official UK subdivision). This is necessary if no information concerning the mean random reflectance of vitrinite (see Section 3.2) is available.

## 9 SPECIFIC PROFILES

## 9.1 $SO_x$ emissions

Sulphur dioxide  $SO_2$  and sulphur trioxide  $SO_3$  are formed in the flame. Emissions of  $SO_2$  and  $SO_3$  are often considered together as  $SO_x$ . Due to the equilibrium conditions at furnace temperature, sulphur trioxide  $SO_3$  normally decomposes to sulphur dioxide  $SO_2$ . Then the amount of  $SO_2$  in the flue gas is approximately 99 %. Therefore,  $SO_x$  is given in this chapter as  $SO_2$ .

## 9.2 $NO_x$ emissions

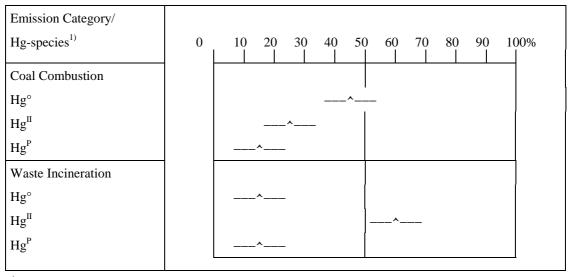

The most important oxides of nitrogen formed with respect to pollution are nitric oxide (NO) and nitrogen dioxide (NO<sub>2</sub>), jointly referred to as NO<sub>x</sub>. The main compound is NO, which contributes over 90 % to the total NO<sub>x</sub>. Other oxides of nitrogen, such as dinitrogen-trioxide (N<sub>2</sub>O<sub>3</sub>), dinitrogen-tetroxide (N<sub>2</sub>O<sub>4</sub>), and dinitrogen-pentoxide (N<sub>2</sub>O<sub>5</sub>), are formed in negligible amounts. Nitrous oxide (N<sub>2</sub>O) is considered separately.

## 9.3 NMVOC emissions

Due to the minor relevance of NMVOC emissions for power plants no split of species is given.

# 9.4 Heavy metal emissions

The heavy metals, which are of most environmental concern, are: arsenic (As), cadmium (Cd), chromium (Cr), copper (Cu), mercury (Hg), nickel (Ni), lead (Pb), selenium (Se) and zinc (Zn). This selection has been laid down by the UN-ECE Task Force on Heavy Metals, the PARCOM/ATMOS programme (cf. /35/) and the HELCOM programme. In the case of heavy oil combustion, vanadium emissions (V) are also of importance. In fly ash particles most of these elements occur as oxides or chlorides. The contribution of various forms of mercury to the emissions from combustion source categories in Europe is given in the following Figure 2:

 $<sup>^{</sup>_{1})}$ Hg $^{\circ}$  elemental form

**Figure 2:** Contribution of various forms of mercury to the emissions from combustion source categories in Europe in 1987 (in % of total) /29/

## 10 UNCERTAINTY ESTIMATES

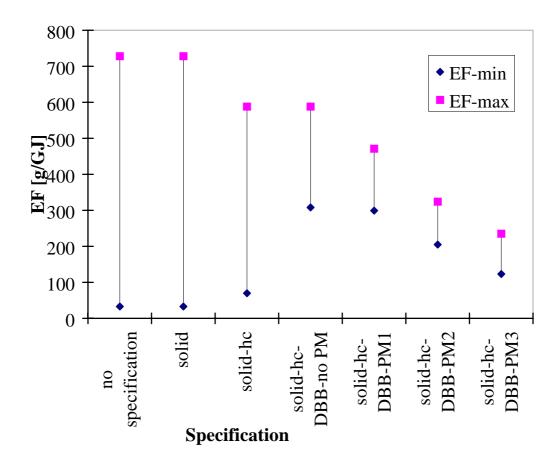

Uncertainties of emission data result from the use of inappropriate or inaccurate emission factors, and from missing or inappropriate statistical information concerning activity data. Uncertainty estimates discussed here are related to the use of emission factors with different background information. At this stage a quantification of the uncertainty related to the use of emission factors is not feasible, due to the limited availability of data. However, the precision of emission estimates can be improved by applying individually determined emission factors.

The aim of the following procedure is to show the Guidebook-user how a lack of information concerning the fuel and technical characteristics of a combustion facility gives rise to a high uncertainty in the allocation of the appropriate emission factor. The whole span of possible emission factors is defined by the specification of the type of fuel used, the type of boiler, and the type of primary and secondary measures. The more information about these topics can be gathered, the smaller the span of possible emission factors becomes.

The following diagram (Figure 3) gives as an example the range of  $NO_x$  emission factors [g/GJ] for pulverised coal combustion depending on the level of specification.

Hg<sup>II</sup> oxidised form

Hg<sup>P</sup> particle-bound

**Figure 3:** Ranges of  $NO_x$  emission factors for the combustion of pulverised coal The level of specification is defined as follows:

- "no information"	- the whole range of combustion sources is taken into account,
- "solid"	- only solid fuels are taken into account,
- "solid-hc"	- only hard coal is considered,
- "solid-hc-DBB-no PM"	- hard coal and combustion technique are taken into account (here dry bottom boiler (DBB), without primary measures),
- "solid-hc-DBB-PM1"	- hard coal, DBB and primary measures are taken into account with a reduction efficiency of $0.2\ ,$
- "solid-hc-DBB-PM2"	- hard coal, DBB and primary measures are taken into account with a reduction efficiency of 0.45 ,
- "solid-hc-DBB-PM3"	- hard coal, DBB and primary measures are taken into account with a reduction efficiency of 0.6.

In Figure 3 a large difference between minimum and maximum emission factors indicates high uncertainties in the allocation of appropriate emission factors. A specification of

emission factors only concerning the type of fuel used (e.g. hard coal) is not sufficient. The range of  $NO_x$  emission factors for the combustion of pulverised coal is significantly reduced if technique related specifications are considered.

# 11 WEAKEST ASPECTS/PRIORITY AREAS FOR IMPROVEMENT IN CURRENT METHODOLOGY

The weakest aspects discussed here are related to the determination of emission factors. Methodological shortcomings are discussed in this section for the main pollutants  $SO_2$ ,  $NO_X$  and heavy metals.

# 11.1 SO<sub>2</sub> emissions

The approach for the determination of SO<sub>2</sub> emission factors is based on a simple mass balance calculation as the formation mechanisms of sulphur dioxide within the boiler depend almost entirely on the sulphur input. Therefore, for the formation of sulphur dioxide, fuel characteristics are of main influence. The accuracy of this approach is determined by the following fuel parameters: lower heating value, fuel sulphur content and sulphur retention in ash (see Equation (5)). The sulphur content and the lower heating value can be highly variable between different fuel categories and can furthermore vary to a large extent within one fuel category. Therefore, default values for sulphur content and lower heating value should be avoided. However, if emission factors for SO<sub>2</sub> have to be calculated, representative values for the sulphur content and the lower heating value should be based on measured data from individual fuel analysis.

The sulphur retention in ash  $\alpha_S$  depends mainly on the content of alkaline components of the fuel. This is only relevant for coal (e.g. CaO, MgO, Na<sub>2</sub>O, K<sub>2</sub>O) and for the case of additive injection. For a more precise determination of  $\alpha_S$ , the Ca/S ratio (amount of calcium/sulphur content of fuel)<sup>8</sup>, the particulate diameter, the surface character of CaO, the temperature (optimum ca. 800 °C), the pressure, the residence time, etc. should be taken into account. Therefore, the assessment of  $\alpha_S$  should be based on an extended set of parameters.

Besides the fuel characteristics, the reduction efficiency and availability of secondary measures are of relevance for the determination of the SO<sub>2</sub> emission factors. Default values are proposed in Table 7, but measured data from individual combustion plants should preferably be used.

# 11.2 NO<sub>X</sub> EMISSIONS

The approach for the calculation of  $NO_X$  emission factors is based on empirical relations. For fuel-NO only fuel characteristics are taken into account. The formation of thermal-NO increases exponentially with combustion temperatures above 1,300 °C (see /56/). At this

Alternatively the Ca/S ratio is defined as the amount of additives related to the sulphur content of the flue gas, and is given for a brown coal fired dry bottom boiler as 2.5 - 5 as an example, for a stationary FBC as 2 - 4, for a circulating FBC < 2 etc. /55/.

stage, no satisfactory result has been achieved to determine the thermal-NO formation by using kinetic equations. For inventory purposes, an empirical parameter  $\gamma$  has been introduced (see Annex 5), which represents the fraction of thermal-NO formed. At this stage default values of  $\gamma$  depending on the type of boiler are given. Further work should focus on a more precise determination of this factor.

Load dependence of the pollutant  $NO_x$  has been taken into account. For old installations a quantitative relation has been given as an example for German power plants. The validity of this relation should be verified for other countries.

Furthermore, the reduction efficiency of primary or secondary measures are of relevance for the determination of  $NO_x$  emission factors. Default values for reduction efficiencies and availabilities are proposed in Tables 10 and 11, but measured data from individual combustion plants should preferably be used.

# 11.3 Heavy metals

Heavy metals undergo complex transformations during the combustion process and downstream of the boiler, referring to e.g. fly ash formation mechanisms. The approaches for the determination of heavy metal emission factors are based on empirical relations, where fuel and technical characteristics are of main influence. The heavy metal contents can be highly variable between different fuel categories (e.g. coal and heavy fuel oil) and can furthermore vary to a large extent within one fuel category (up to 2 orders of magnitude). Therefore, default values for heavy metal contents in fuel should be avoided and measured values should be used as far as possible.

For inventory purposes, parameters, such as enrichment factors, fractions of fly ash leaving the combustion chamber, fraction of heavy metals emitted in gaseous form, have been introduced. Further work should be invested into a more precise determination of these parameters. In addition, it should be taken into account, that the reduction efficiency of (dust) abatement measures depends on the heavy metal. Heavy metal specific reduction efficiencies should be determined.

# 11.4 Other aspects

Emission factors for SO<sub>2</sub>, NO<sub>2</sub> and CO, whether calculated or given in the tables, are related to full load conditions. In order to assess the relevance of start-up emissions, a detailed investigation has been accomplished by using measured values from different types of boiler (see also Annex 15). The qualitative and quantitative statements obtained in this approach should be verified.

The emission factors have been determined by considering the pollutants separately. Possible mutual interactions between the formation mechanisms of different pollutants (e.g. NO and  $N_2O$ ) have been neglected and should be assessed in further work.

## 12 SPATIAL DISAGGREGATION CRITERIA FOR AREA SOURCES

This section is not relevant for combustion plants considered as point sources.

#### 13 TEMPORAL DISAGGREGATION CRITERIA

The temporal disaggregation of annual emission data (top-down approach) provides a split into monthly, weekly, daily and hourly emission data. Temporal disaggregation of annual emissions released from combustion plants as point sources can be obtained from the temporal change of the production of electrical power or the temporal change of the consumption, taking into account a split into:

- summer and winter time,
- working days and holidays,
- standstill times,
- times of partial load behaviour and
- number of start-ups / type of load design.

This split should be carried out for defined categories of power plants which take into account the main relevant combinations of types of fuel used and types of boiler installed (similar split as used for the emission factor Tables in Section 8).

The disaggregation of annual emissions into monthly, daily or hourly emissions can be based on a step-by-step approach /76/ according to the following equations:

- Monthly emission:

$$E_{M_n} = \frac{E_A}{12} \cdot f_n \tag{25}$$

 $E_{M_n}$  Emission in month n; n = 1, ..., 12 [Mg]

E<sub>A</sub> Annual emission [Mg]

 $f_n$  Factor for month n; n = 1, ..., 12 []

- Daily emission:

$$E_{D_{n,k}} = \frac{E_{M_n}}{D_k} \cdot f_k \cdot \frac{1}{CF_n}$$
 (26)

 $E_{D_{n,k}} \qquad \quad \text{Emission of day $k$ in month $n$; $k=1,...,D_k$; $n=1,...,12$ [Mg]}$ 

 $E_{M_n}$  Emission in month n; n = 1, ..., 12 [Mg]

 $D_k$  Number of days in month n [ ]

 $f_k$  Factor for day k;  $k = 1, ..., D_k$  []

CF<sub>n</sub> Correction factor for month n [ ]

- Hourly emission:

$$E_{H_{n,k,l}} = \frac{E_{D_{n,k}}}{24} \cdot f_{n,l} \tag{27}$$

 $E_{H_{n\,k\,1}} \qquad \text{Emission in hour 1 in day $k$ and month $n$; $l=1,\,...,\,24$; $k=1,\,...,\,D_k$; $n=1,\,...,\,12$ [Mg]}$ 

 $E_{D_{n,k}}$  Emission of day k in month n; k = 1, ...,  $D_k$ ; n = 1, ..., 12 [Mg]

 $f_{n,l}$  Factor for hour 1 in month n; l = 1, ..., 24; n = 1, ..., 12

D<sub>k</sub> Number of days in month n []

The factors (relative activities) for month  $f_n$ , day  $f_k$  and hour  $f_{n,l}$  can be related e.g. to the total fuel consumption or the net electricity production in public power plants. Figure 4 gives an example of a split for monthly factors based on the fuel consumption e.g. for Public Power Plants:

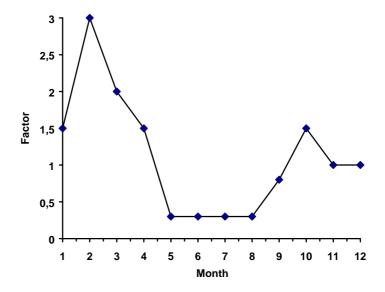

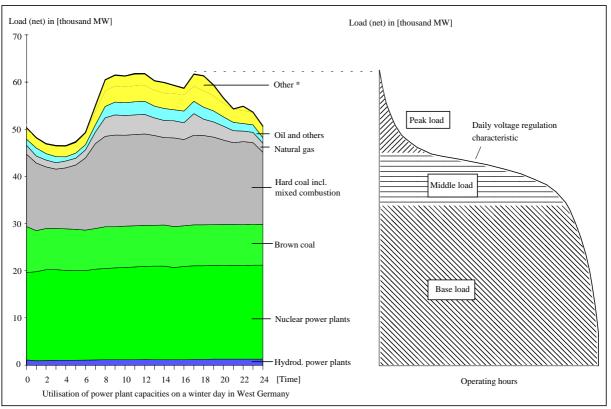

Figure 4: Example of monthly factors for total fuel consumption in Public Power Plants

A split concerning the load design, which determines the annual number of start-ups can be given as follows (see also Table 11):

- Base load: The boiler/plant is normally in continuous operation during the year; startups occur relatively seldom (ca. 15 times per year) depending on maintenance periods which occur mostly in summer. The fuel mostly used in base load boilers is brown coal.
- Middle load: The boiler/plant is in operation in order to meet the energy demand on working days (Monday until Friday); start-ups can occur up to 150 times per year. The fuel mostly used in middle load boilers is hard coal.
- Peak load: The boiler/plant is in operation in order to meet the short term energy demand; start-ups can occur up to 200 times per year. The fuels mostly used in peak load boilers are gas or oil.

The allocation of power plants to the different load designs is given as an example in Figure 5.

\*Other includes: Storage pump power plants, power supply from industry etc.

**Figure 5:** Load variation and arrangement of power plants according to the voltage regulation characteristic (cf. /117/, /118/).

It can be assumed that all power plants of a country with the same allocation of fuel, boiler and load have the same temporal behaviour.

## 14 ADDITIONAL COMMENTS

## 15 SUPPLEMENTARY DOCUMENTS

## 15.1 Computer programme

A computer programme for the calculation of SO<sub>2</sub> and NO<sub>2</sub> emission factors for pulverised coal combustion has been designed, and is available on floppy disc. It has been designed under MICROSOFT EXCEL 4.0 (English version). Default values for the required input data are proposed to the user; a detailed users manual is given in Annex 14. For example, NO<sub>X</sub> concentrations in [mg/m³] were calculated with the computer programme and presented

together with the emission factors in [g/GJ] as listed in Annexes 10 and 11. An integral part of the computer programme is the calculation of the flue gas volume as given in Annex 6.

## 15.2 LIST OF ANNEXES

Annex 1: Example of different possible considerations of boilers as a common plant Annex 2: Determination of SO<sub>2</sub> emission factors (flow sheet) Annex 3: Determination of SO<sub>2</sub> emission factors (description) Annex 4: Determination of NO<sub>x</sub> emission factors (flow sheet) Annex 5: Determination of NO<sub>X</sub> emission factors (description) Annex 6: Determination of the specific flue gas volume (flow sheet and description) Annex 7: Composition and lower heating value (H<sub>u</sub>) of hard coal in coal mining countries Annex 8: Composition and lower heating value (H<sub>u</sub>) of brown coal in coal mining countries Annex 9: Conditions for exemplary calculation of NO<sub>x</sub> emission factors Annex 10: Emission factors and flue gas concentrations for NO<sub>X</sub> obtained by model calculations (see Annexes 4 and 5) for hard coal (see Annex 7) Annex 11: Emission factors and flue gas concentrations for NO<sub>x</sub> obtained by model calculations (see Annexes 4 and 5) for brown coal (see Annex 8) Annex 12: Comparison between measured and calculated SO<sub>2</sub> and NO<sub>x</sub> emission data Annex 13. Sensitivity analysis of the computer programme results Annex 14: Users' manual for the emission factor calculation programme (for version September, 1995) Annex 15: Determination of start-up emissions and start-up emission factors.

#### 16 VERIFICATION PROCEDURES

List of abbreviations

As outlined in the chapter "Concepts for Emission Inventory Verification", different general verification procedures can be recommended. The aim of this section is to develop specific verification procedures for emission data from combustion plants as point sources. The

Annex 16:

verification procedures considered here are principally based on verification on a national and on a plant level. Moreover, it can be distinguished between the verification of activity data, of emission factors and of emission data.

## 16.1 Verification on a national level

For combustion plants as point sources, emissions and activities have to be verified. The total emissions from point sources are added together to obtain national total emissions (bottom-up approach). These national total emissions should be compared to emission data derived independently (top-down approach). Independent emission estimates can be obtained by using average emission factors and corresponding statistical data like the total fuel input for all sources, total thermal capacity, total heat or power produced, or by using emission estimates from other sources (e.g. organisations like energy agencies).

The total fuel consumption should be reconciled with energy balances, which often have break-downs for large point sources (e.g. electricity, heat generation and industrial boilers). Furthermore, the total number of plants installed as well as their equipment should be checked with national statistics.

Emission density comparisons can be achieved through comparison of e.g. emissions per capita or emissions per GDP with those of countries with a comparable economic structure.

# 16.2 Verification on a plant level

It should firstly be verified that separate inventories have been compiled for boilers, stationary engines, and gas turbines (according to SNAP code). The verification at plant level relies on comparisons between calculated emission factors and those derived from emission measurements. An example for such a comparison is given in Annex 12.

**Annex 1:** Example of different possible considerations for boilers as a common plant

Annex 2: Determination of SO<sub>2</sub> emission factors (flow sheet, for description see Annex 3)

### **Annex 3:** Determination of SO<sub>2</sub> emission factors (description)

The calculation procedure is performed in three steps:

I The fuel sulphur reacts stoichiometrically with oxygen  $O_2$  to sulphur dioxide  $SO_2$ . Default values for the sulphur content  $C_{S_{fuel}}$  in hard and brown coal are given in Annexes 7 and 8. The result is the maximum attainable amount of sulphur dioxide  $C_{SO_{2,max}}$  given by:

$$C_{SO_{2_{\text{max}}}} = 2 \cdot C_{S_{\text{fuel}}} \tag{3-1}$$

 $C_{S_{\text{fuel}}}$  sulphur content of fuel (in mass element/mass fuel [kg/kg])

 $C_{SO_{2\,max}} \quad \text{maximum attainable amount of sulphur dioxide (in mass pollutant/mass fuel [kg/kg])}$ 

II The maximum attainable amount of sulphur dioxide  $C_{SO_{2,max}}$  is corrected by the sulphur retention in ash  $\alpha_s$ . As a result, the real boiler emission of sulphur dioxide  $C_{SO_{2,boiler}}$  fuel is obtained:

$$C_{SO_{2b-silor}} = C_{SO_{2-max}} \cdot (1 - \alpha_s)$$
(3-2)

 $C_{SO_{2 \text{boiler}}}$  real boiler emission of sulphur dioxide (in mass pollutant/mass fuel [kg/kg])

 $C_{SO_{2,max}} \quad \text{maximum attainable amount of sulphur dioxide (in mass pollutant/mass fuel [kg/kg])}$ 

 $\alpha_S$  sulphur retention in ash []

The sulphur retention in ash depends e.g. on fuel characteristics and temperature inside the boiler. If there is no data for  $\alpha_S$  available, default values for various fuels are given in Table 8.

III The boiler emission of sulphur dioxide is corrected by the reduction efficiency  $\eta$  and availability  $\beta$  (for definition of  $\beta$  see Section 3.2) of the secondary measure installed, according to:

$$C_{SO_{2-cor}} = C_{SO_{2-coilor}} \cdot (1 - \eta \cdot \beta)$$
(3-3)

 $C_{SO_{2sec}}$  sulphur dioxide downstream secondary measure (in mass pollutant/mass fuel [kg/kg])

 $C_{SO_{2\,hoiler}}$  real boiler emission of sulphur dioxide (in mass pollutant/mass fuel [kg/kg])

η reduction efficiency of secondary measure []

 $\beta$  availability of secondary measure []

The result is called secondary sulphur dioxide  $C_{SO_{2,sec}}$ . If there is no data for  $\eta$  and  $\beta$  available, default values for various flue gas desulphurisation techniques (FGD) are given in Table 7.

The obtained  $C_{SO_{2sec}}$  value is converted to  $C_{SO_2}$  in flue gas and to the emission factor  $EF_{SO_2}$  according to the following Equations:

$$C_{SO_2} = C_{SO_{2,sec}} \cdot \frac{1}{V_{FG}} \cdot 10^6$$
 (3-4)

$$EF_{SO_2} = C_{SO_{2,sec}} \cdot \frac{1}{H_u} \cdot 10^6$$
 (3-5)

 $C_{SO_2}$  sulphur dioxide in flue gas (in mass pollutant/volume flue gas [mg/m<sup>3</sup>])

 $C_{SO_{2ssc}}$  sulphur dioxide downstream of secondary measure (in mass pollutant/mass fuel [kg/kg])

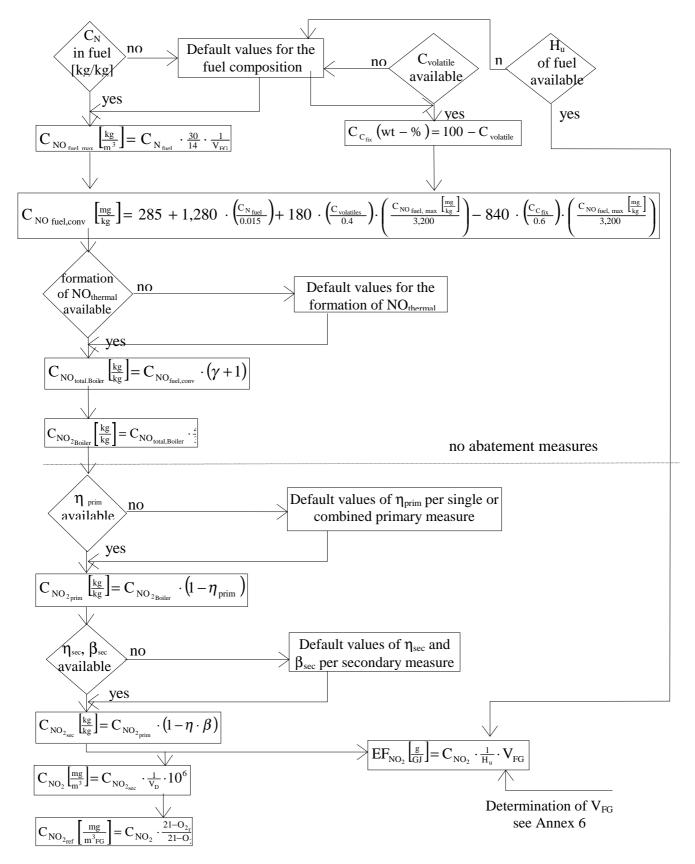

V<sub>FG</sub> dry flue gas volume volume (in volume flue gas/mass fuel [m<sup>3</sup>/kg])

EF<sub>SO2</sub> emission factor for sulphur dioxide [g/GJ]

H<sub>u</sub> lower heating value [MJ/kg]

The dry flue gas volume  $V_{FG}$  can be determined according to Annex 6. Emission data in  $[mg/m^3]$  are useful to compare measured and calculated values. The same equations are used for the unit conversion of  $C_{SO_{2boiler}}$ . Default values for the lower heating values of hard and brown coal are given in Annexes 7 and 8.

**Annex 4**: Determination of NO<sub>x</sub> emission factors (flow sheet, for description see Annex 5)

# **Annex 5:** Determination of $NO_X$ emission factors (description)

The determination of  $NO_x$  emission factors takes into account the formation of fuel-NO and thermal-NO. The formation of fuel-NO is based on fuel parameters. But the total amount of fuel-nitrogen cannot be completely converted into fuel-NO (as obtained in Equation (5-1)). Therefore, the realistic formation of fuel-NO is described by an empirical relation (see Equation (5-2)). The formation of thermal-NO is expressed by an an additional fraction which depends on the type of boiler.

The calculation procedure of the  $NO_X$  emission factor is performed in three steps: In the first step the maximum NO emission resulting from stoichiometric conversion of fuel nitrogen is calculated. The NO emission obtained is further corrected by taking into account the formation of thermal-NO. NO is converted into  $NO_2$  and primary and secondary measures are taken into account in steps two and three.

I The fuel-nitrogen reacts in a stoichiometric manner with oxygen  $O_2$  to form nitrogen oxide. The default values for the nitrogen content  $C_{N_{2_{\text{fuel}}}}$  in hard and brown coal are given in Annexes 7 and 8. The maximum attainable amount of fuel nitrogen oxide  $C_{NO_{\text{fuel.max}}}$  is obtained:

$$C_{NO_{fuel_{max}}} = C_{N_{fuel}} \cdot \frac{30}{14} \cdot \frac{1}{V_{EG}}$$

$$(5-1)$$

 $C_{NO_{fuel,max}}$  maximum attainable amount of fuel nitrogen oxide (in mass pollutant/volume flue gas [kg/m $^3$ ])

 $C_{N_{f_{nel}}}$  nitrogen content in fuel (in mass nitrogen/mass fuel [kg/kg])

 $V_{FG}$  specific flue gas volume (in volume flue gas/mass fuel  $[m^3/kg]$ )<sup>9</sup>

The fuel-nitrogen content  $C_{N_{fuel}}$  is not completely converted into  $C_{NO_{fuel}}$ . The converted part of fuel-nitrogen to fuel-NO  $C_{NO_{fuel,conv}}$  can be determined by the following empirical formula /50, 51/ related to zero percent of oxygen in dry flue gas:

$$C_{\text{NO}_{\text{fuel} \, conv}} = 285 + 1,280 \left( \frac{C_{\text{N}_{\text{fuel}}}}{0.015} \right) + 180 \left( \frac{C_{\text{volatiles}}}{0.4} \right) \left( \frac{C_{\text{NO}_{\text{fuel} \, max}}}{3,200} \right) - 840 \left( \frac{C_{\text{C}_{\text{fix}}}}{0.6} \right) \left( \frac{C_{\text{NO}_{\text{fuel} \, max}}}{3,200} \right)$$
 (5-2)

 $C_{NO_{fuel,conv}}$  fuel-NO released (in mass pollutant/mass flue gas [mg/kg])<sup>2</sup>

 $C_{N_{\text{\tiny max}}}$  nitrogen content in fuel (in mass nitrogen/mass fuel [kg/kg]), maf

 $C_{volatiles}$  fuel content of volatiles (in mass volatiles/mass fuel [kg/kg]), maf

 $C_{
m NO_{fuel,max}}$  maximum attainable amount of fuel nitrogen oxide (in mass pollutant/mass flue gas [mg/kg]) $^{10}$ 

 $C_{C_{fiv}}$  fixed carbon in fuel (in mass carbon/ mass fuel [kg/kg]), maf

\_

The programme calculates stoichiometrically the specific flue gas volume based on the complete fuel composition.

Note:  $C_{NO.fuel.max}$  and  $C_{NO.fuel.conv}$  are given in the unit (mass pollutant/mass flue gas [mg/kg]). For the conversion between (mass pollutant/mass flue gas [mg/kg]) and (mass pollutant/volume flue gas [kg/m3]) the flue gas density (in mass flue gas/volume flue gas [kg/m³]) has to be taken into account, which is calculated stoichiometrically from the fuel composition within the computer programme.

The fixed carbon in the fuel is determined according to the equation  $C_{C_{\rm fix}}=1$  -  $C_{\rm volatiles}$ . Equation (5-2) is valid for nitrogen oxide emissions from premixed flames; the coefficient of correlation is  $r^2=0.9$  for 20 coals and  $r^2=0.75$  for 46 coals /51/. The data has been obtained by field and pilot-scale measurements. Basically tests are conducted in a 70,000 Btu/hr (20.5 kW) refractory lined furnace with variable heat extraction. Coal was injected through special configurations. A nozzle produces an uniform heterogeneous mixture of coal and air prior to combustion and represents the limit of intensely mixed flames produced with high swirl. Further tests have been established in large scale furnaces. The results from all measurements combined with additional information based on literature data have been used to establish a correlation which predicts the relative dependence of nitrogen oxide emissions on fuel properties. /51/ Further calculations with Equation (5-2) based on measured data have been provided in /50/. The comparison between measured and calculated values has shown that the results from Equation (5-2) are very good for high volatile coals and are satisfactory for medium volatile coals /50/.

Assuming that the formation of fuel-NO is much more important than the formation of thermal-NO (fuel-NO amounts to 70 - 90 %), the content of thermal-NO formed can be expressed as a fraction  $\gamma$  (where  $\gamma$  depends on the type of boiler) of NO<sub>fuel</sub>. The total content of nitrogen oxide formed in the boiler  $C_{NO_{total,boiler}}$  is given by:

$$C_{NO_{totalboiler}} = C_{NO_{fuel_{conv}}} + C_{NO_{thermal}} = C_{NO_{fuel_{conv}}} \cdot (1 + \gamma)$$
(5-3)

 $C_{NO_{total boiler}}$  total content of nitrogen oxide formed in the boiler (in mass pollutant/mass flue gas [kg/kg])

C<sub>NO<sub>ful</sub></sub> fuel-NO released (in mass pollutant/mass flue gas [kg/kg])

C<sub>NO.</sub> content of thermal-NO formed (in mass pollutant/mass flue gas [kg/kg])

γ fraction for thermal-NO formed []

The following default values for  $\gamma$  can be recommended: DBB  $\gamma$  = 0.05, WBB  $\gamma$  = 0.3. Furthermore, the amount of thermal-NO can be influenced by load (see also Section 11.2).

The total boiler emissions of nitrogen dioxide  $C_{NO_{2 \text{ boiler}}}$  can be calculated as follows:

$$C_{NO_{2\text{boiler}}} = C_{NO_{\text{total}_{\text{boiler}}}} \cdot \frac{46}{30}$$
 (5-4)

 $C_{NO_{2_{boiler}}}$  total content of nitrogen dioxide formed in the boiler (in mass pollutant/mass flue gas [kg/kg])  $C_{NO_{total_{boiler}}}$  total content of nitrogen oxide formed in the boiler (in mass pollutant/mass flue gas [kg/kg])

II The total boiler content of nitrogen dioxide given by  $C_{NO_{2.boiler}}$  is reduced by taking into account primary measures with the reduction efficiency  $\eta_{prim}$ . The result is the content of primary nitrogen dioxide  $C_{NO_{2.mim}}$ :

$$C_{NO_{2\text{prim}}} = C_{NO_{2\text{boiler}}} \cdot (1 - \eta_{\text{prim}})$$
 (5-5)

 $C_{NO_{2\,\text{min}}}$  content of primary nitrogen dioxide (in mass pollutant/mass flue gas [kg/kg])

 $C_{NO_{2_{\text{builled}}}}$  total content of nitrogen dioxide formed in the boiler (in mass pollutant/mass flue gas [kg/kg])

 $\eta_{\text{prim}}$  reduction efficiency of primary measure(s) [ ]

As there is only incomplete data available for reduction efficiencies, default values are given for the individual and relevant combinations of primary measures for different types of boilers and fuels (see Table 8). In the case of combined primary measures with known individual reduction efficiencies  $\eta_{prim,1}$ ,  $\eta_{prim,2}$ , etc., the following equation can be used:

$$C_{NO_{2_{\text{prim}}}} = C_{NO_{2_{\text{boiler}}}} \cdot (1 - \eta_{\text{prim}1}) \cdot (1 - \eta_{\text{prim}2}) \cdot (1 - \eta_{\text{prim}3})$$

$$(5-6)$$

 $C_{NO_{2prim}}$  content of nitrogen dioxide taking into account primary measures (in mass pollutant/mass flue gas [kg/kg])

C<sub>NO<sub>2k-11-2</sub></sub> total content of nitrogen dioxide formed in the boiler (in mass pollutant/mass flue gas [kg/kg])

 $\eta_{\text{prim}_k} \quad \ \, \text{individual reduction efficiency of primary measure } k \, [ \, ]$ 

It should be taken into account, that the reduction efficiencies of primary measures are not independent of each other.

III The emission of primary nitrogen dioxide  $C_{NO_{2,prim}}$  is corrected by the reduction efficiency  $\eta_{Sec}$  [ ] and the availability  $\beta_{Sec}$  [ ] (for definition of  $\beta$  see Section 3.2) of the secondary measure installed, according to:

$$C_{NO_{2...}} = C_{NO_{2...}} \cdot (1 - \eta_{sec} \cdot \beta_{sec})$$
 (5-7)

 $C_{NO_{2sec}}$  nitrogen dioxide downstream of secondary measure (in mass pollutant/mass flue gas [kg/kg])

 $C_{NO_{2prim}}$  content of nitrogen dioxide taking into account primary measures (in mass pollutant/mass flue gas  $\lceil kg/kg \rceil$ )

 $\eta_{sec}$  reduction efficiency of secondary measure []

 $\beta_{sec}$  availability of secondary measure [ ]

If there is no data for  $\eta_{sec}$  and  $\beta_{sec}$  available, default values for various DeNOx techniques are given in Table 9.

The obtained value of  $C_{NO_{2,sec}}$  is converted into  $C_{NO_{2}}$  and into the emission factor  $EF_{NO_{2}}$  according to the following equations:

$$C_{NO_2} = C_{NO_{2_{sec}}} \cdot \frac{1}{V_D} \cdot 10^6$$
 (5-8)

$$EF_{NO_2} = C_{NO_2} \cdot \frac{1}{H_{in}} \cdot V_{FG}$$
 (5-9)

C<sub>NO<sub>3</sub></sub> nitrogen dioxide in flue gas (in mass pollutant/volume flue gas [mg/m<sup>3</sup>])

 $C_{NO_{2sec}}$  nitrogen dioxide downstream of secondary measure (in mass pollutant/mass flue gas [kg/kg])

 $\begin{array}{ll} V_D & \quad \text{dry flue gas volume (in volume flue gas/mass flue gas } [\text{m}^3/\text{kg}]) \\ V_{FG} & \quad \text{specific dry flue gas volume (in volume flue gas/mass fuel } [\text{m}^3/\text{kg}]) \end{array}$ 

 $EF_{NO}, \qquad emission \ factor \ for \ nitrogen \ dioxide \ [g/GJ]$ 

H<sub>u</sub> lower heating value [MJ/kg]

The specific dry flue gas volume  $V_{FG}$  can be determined according to Annex 6. Emission data expressed in  $[mg/m^3]$  are used for comparing measured and calculated values. Default values for lower heating values for hard and brown coal are given in Annexes 7 and 8.

# **Annex 6:** Determination of the specific flue gas volume (flow sheet and description)

The specific flue gas volume has to be determined in order to convert the emission factors, which have been obtained in [g/GJ], into [mg/m³], which allows a comparison to measured data. The approach is given in the following flow sheet:

Activities 010101 - 010105 ps0

For the determination of the flue gas volume, the elemental analysis of the fuel (content of carbon  $C_C$ , sulphur  $C_S$ , hydrogen  $C_H$ , oxygen  $C_{O_2}$  and nitrogen  $C_N$  (maf)) has to be known. If no data of the elemental analysis is available, default values of hard and brown coals are proposed in Annexes 7 and 8. The volume of oxygen required for a stoichiometric reaction  $V_{O_{2_{min}}}$  can be determined as follows:

$$V_{O_2} = 1.864 \cdot C_C + 0.700 \cdot C_S + 5.553 \cdot C_H - 0.700 \cdot C_{O_2}$$
(6-1)

 $V_{O_{2_{min}}}$  volume of oxygen required for stoichiometric reaction (in volume oxygen/mass fuel  $[m^3/kg]$ )

C<sub>C</sub> content of carbon in fuel (in mass carbon/mass fuel [kg/kg])

 $C_S$  content of sulphur in fuel (in mass sulphur/mass fuel [kg/kg])

 $C_{H}$  content of hydrogen in fuel (in mass hydrogen/mass fuel [kg/kg])

C<sub>O</sub>, content of oxygen in fuel (in mass oxygen/mass fuel [kg/kg])

The constants in Equation (6-1) represent stoichiometric factors for the volume of oxygen required for the combustion of 1 kg carbon, sulphur or hydrogen in  $[m^3/kg]$ . The corresponding volume of nitrogen in the air  $V_{N_{air}}$  is given by Equation (6-2):

$$V_{N_{air}} = V_{O_{2min}} \cdot \frac{79}{21} \tag{6-2}$$

 $V_{N_{air}}$  volume of nitrogen in the air (in volume nitrogen/mass fuel [m<sup>3</sup>/kg])

 $V_{O_{2_{min}}}$  volume of oxygen required for stoichiometric reaction (in volume oxygen/mass fuel [m<sup>3</sup>/kg])

The specific dry flue gas volume at 0 % oxygen  $V_{FG}$  can be determined by using Equation (6-3):

$$V_{FG} = 1.852 \cdot C_C + 0.682 \cdot C_S + 0.800 \cdot C_N + V_{N_{ch}}$$
(6-3)

V<sub>FG</sub> specific dry flue gas volume (in volume flue gas/mass fuel [m³/kg])

C<sub>C</sub> content of carbon in fuel (in mass carbon/mass fuel [kg/kg])

C<sub>S</sub> content of sulphur in fuel (in mass sulphur/mass fuel [kg/kg])

C<sub>N</sub> content of nitrogen in fuel (in mass nitrogen/mass fuel [kg/kg])

 $V_{N_{air}}$  volume of nitrogen in the air (in volume nitrogen/mass fuel [m<sup>3</sup>/kg])

The constants in Equation (6-3) represent stoichiometric factors for the volume of oxygen required for the combustion of 1 kg carbon, sulphur or nitrogen in  $[m^3/kg]$ . The obtained values of  $V_{FG}$  at 0 % oxygen are converted to the reference content of oxygen in flue gas according to Equation (6-4):

$$V_{FG_{ref}} = V_{FG} \cdot \frac{21 - O_2}{21 - O_{2_{ref}}}$$
 (6-4)

V<sub>FG...</sub> volume of specific flue gas under reference conditions (in volume flue gas/mass fuel [m³/kg])

V<sub>FG</sub> volume of specific flue gas obtained (in volume flue gas/mass fuel [m<sup>3</sup>/kg])

O<sub>2</sub> content of oxygen in the flue gas obtained [%]

 ${
m O_{2_{ref}}}$  content of oxygen in the flue gas under reference conditions [%]

### **Annex 9:** Conditions for exemplary calculation of NO<sub>x</sub> emission factors

Annex 9 presents the values which have been chosen for the calculation of  $NO_x$  emission factors (according to Section 4.2.1). The results of the calculations are given in the following Annexes 10 (for hard coal) and 11 (for brown coal). Both annexes contain emission factors in [g/GJ] as well as concentrations in [mg/m³] which have been determined under the conditions given in Table 9-1:

**Table 9-1:** Selected input parameters for model calculations determining  $NO_X$  emission factors as given in Annexes 10 and 11

Type of coal <sup>1</sup> )	Type of boiler	Fraction of thermal NO NO <sub>th</sub> [ ]	Reduction efficiency of primary measures $\eta_{prim}^{2}$ [ ]	Reduction efficiency of secondary measures $\eta_{sec}$ [ ]	Availability $\beta_{sec}$ [ ]
hc	DBB	0,05	LNB 0,20 LNB/SAS 0,45	SCR 0,8	0,99
			LNB/OFA 0,45 LNB/SAS/OFA 0,60		
	WBB	0,30	LNB 0,20 LNB/SAS 0,45 LNB/OFA 0,40	SCR 0,8	0,99
			LNB/SAS/OFA 0,60		
bc	DBB	0,05	LNB 0,20 LNB/SAS 0,45	-	-
			LNB/OFA 0,40 LNB/SAS/OFA 0,60		

<sup>1)</sup> Elementary analyses of hard and brown coal are given in Annexes 7 and 8.

For individual calculations of  $NO_X$  emission factors, the computer programme (users' manual see Section 15 and Annex 14) can be used.

<sup>2)</sup> The reduction efficiency is given as an example for selected primary measures (see Section 4.2). Abbreviations: hc = hard coal, bc = brown coal

<sup>1)</sup> PM = primary measures as given in Table 8

### **Annex 12:** Comparison between measured and calculated $SO_2$ and $NO_x$ emission data

The proposed methodology for the determination of  $SO_2$  and  $NO_x$  emission factors is described in the Sections 4.1 and 4.2. Calculated flue gas concentrations in  $[mg/m^3]$  have been used for the derivation of emission factors in [g/GJ]. A comparison of measured concentrations in combustion plants in  $[mg/m^3]$  with calculated concentrations in  $[mg/m^3]$  can be used for verification purposes.

A comparison of measured concentrations with calculated flue gas concentrations downstream of the boiler is given as an example for some power plants in Table 12-1.

**Table 12-1:** Comparison of measured and calculated flue gas concentrations in raw gas of the boiler (taking into account primary reduction measures)<sup>13)</sup>

values refer to full load conditions

n. d. = no data available

n.d. = no data available

The values in Table 12-1 are compared in the Figure 12-1 below:

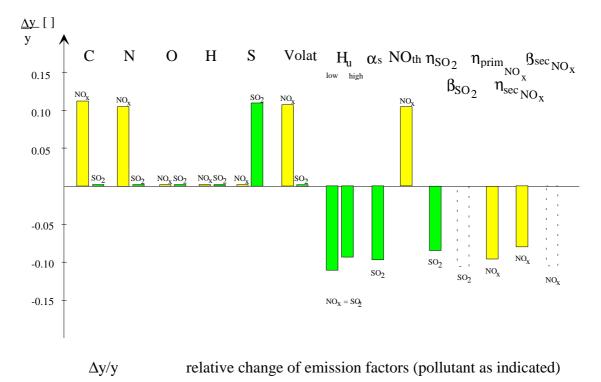

**Figure 12-1:** Comparison of measured flue gas concentrations [mg/m<sup>3</sup>] and calculated flue gas concentrations [mg/m<sup>3</sup>] downstream of the boiler

The comparison of measured flue gas concentrations and calculated flue gas concentrations shows that most values are scattered close to the middle axis.

Good correlations between measured and calculated values have been obtained for calculations which are only based on plant specific data provided by power plant operators. But for most calculations a mixture of plant specific data and default values for missing parameters has been used which leads to deviations from the middle axis. In particular strong differences occur for  $SO_2$  emissions which show a tendency to be overestimated. The tendency can be explained by assumptions with regard to default values; e.g. the sulphur retention in ash varies greatly depending on the data availability.

### **Annex 13:** Sensitivity analysis of the computer programme results

A sensitivity analysis was carried out with all model input parameters used. The 14 input parameters (fuel content of carbon C, nitrogen N, oxygen O, hydrogen H, sulphur S, volatiles Volat, lower heating value  $H_u$ , sulphur retention in ash  $\alpha_s$ , fraction of thermal nitrogen oxide NO<sub>th</sub>, reduction efficiency  $\eta$  and availability  $\beta$  of abatement measures) was arranged with respect to their influence on SO<sub>2</sub> and NO<sub>x</sub> emissions. Each input parameter was varied by  $\pm 10$  % except  $\beta_{SO2}$  and  $\beta_{sec.NOx}$  which were varied only by - 4 % (dashed line); the variation of the calculated emission factors is presented in Figure 13-1.

**Figure 13-1:** Sensitivity analysis of the emission factor calculation programme results for pulverised coal combustion

For emission factors of  $SO_2$  the sulphur content of fuel and the sulphur retention in ash are highly relevant. For emission factors of  $NO_X$  the fuel content of nitrogen, carbon and volatiles as well as the reduction efficiency of primary measures are highly relevant. The fuel contents of oxygen and hydrogen are not relevant. The relative change of emission factors concerning the lower heating value can be described for  $SO_2$  and  $NO_X$  as an exponential curve: that means that uncertainties at lower levels of the heating values (e.g. for brown coal) influence the result stronger. The efficiency of secondary measures is of slightly less influence than the efficiency of primary measures. The availability of secondary measures is marked with a dashed line in Figure 13-1; a 4 % variation of this parameter has shown significant influence.

**Annex 14:** Users' manual for the emission factor calculation programme (for September 1995 version)

### Determination of SO<sub>2</sub> and NO<sub>x</sub> emission factors for large combustion plants

### 1 Computer specifications

This programme requires MICROSOFT WINDOWS 3.1, a 3½" floppy disc drive, and at least 200 Kbyte on the hard disc. The programme has been designed in MICROSOFT EXCEL 4.0 - English Version.

#### 2 Installation

The floppy disc received contains 19 files. All these files have to be installed on the hard disc. The following users' guide is stored under README.DOC (written with MICROSOFT WORD FOR WINDOWS 2.1).

The software has to be installed on your hard disk "C" by using the following procedure:

- Create a new sub-directory with the name 'POWER\_PL' by following the instructions:
  - in DOS go to C:\
  - type: MD POWER\_PL
  - hit the <ENTER>-key
  - change into this sub-directory by typing: CD POWER\_PL
  - hit the <ENTER>-key.
- To copy all the files from your floppy disc into the sub-directory 'POWER\_PL' proceed as follows:
  - insert your disk into slot A (or B) of your PC
  - type COPY A: (or B:)\\*.\*
  - hit the <ENTER>-key.

The installation of the programme is then complete.

### *3 How to work with the programme*

### 3.1 Start the programme

- Start MICROSOFT WINDOWS 3.1 and MICROSOFT EXCEL 4.0 English Version (or MICROSOFT EXCEL 5.0 English Version).
- In 'FILE' 'OPEN', go to hard disk 'C' and activate the sub-directory 'POWER\_PL'. Then you will see all the necessary files in the programme in the left window.
- Choose the file 'POWER\_PL.XLW' and hit the <ENTER>-key.
- Then the programme opens all the tables and macros needed.

#### 3.2 Further proceedings with the programme

- When you see the first screen please type 'Ctrl'-'a' (or 'Strg'-'a') to start the programme. By hitting these two keys you start a macro, which takes you through all the levels of the programme. The input data for the programme are divided into background tables for the fuel used, for SO<sub>2</sub>-specification and NO<sub>x</sub>-specification.

### Fuel data input

- First the programme asks for an identification of the model run. You are free to put in the name of the power plant, type of boiler, type of fuel (e. g. Heilbronn dry bottom boiler hard coal).
- The next window requests the type of coal (hard coal or lignite).
- The programme asks you to choose one of the fuel compositions listed. Select one of them by typing the corresponding number and hitting the 'OK'-key on the screen<sup>1)</sup>. If the default values of the given fuel compositions do not correspond with your power plant, you have the possibility of putting in corrected values by choosing the last line of the table (line 17 or 10). Then the programme asks you to enter in the individual values. The values given by the 'question-window' can be kept by hitting the 'OK'-key on the screen.
- Then the programme asks for the water content of the fuel and the reference-content of oxygen in the flue gas. The value given by the 'question-window' can be retained by hitting the 'OK'-key on the screen.

# SO<sub>2</sub> data specification

- The programme asks you to choose one of the listed numbers as a value for the sulphur retention in ash. Please select one of them by typing the corresponding number and hitting the 'OK'-key on the screen1). If the default values for the sulphur retention in ash do not correspond with your power plant, you have the possibility of putting in corrected values by choosing the last line of the table (line 3). Then the programme asks you to put in the value.
- The programme asks you to choose one of the listed secondary measures  $SO_2$ . Please select one of them by typing the corresponding number and hitting the 'OK'-key on the screen<sup>1</sup>). If the default values of the efficiencies and availabilities of the secondary measures given do not correspond with those of your power plant, you have the possibility of putting put in corrected values by choosing the last line of the table (line 9). Then the programme asks you to put in the individual values.

At this point the calculations for SO<sub>2</sub> are finished.

### NO<sub>x</sub> data specification

- The programme proceeds with the calculations of NO<sub>2</sub> by asking for a value for NO<sub>thermal</sub><sup>1</sup>. At this stage, the thermal NO (NOthermal) has to be put in as an exogenious value as given in the table. You have the possibility of putting in a new value by following the instructions on the screen.

- The next window requests the type of boiler (wet bottom boiler WBB- dry bottom boiler DBB).
- Then you have to choose a type of combination of primary measure installed. For some primary measures, reduction efficiencies are given as default values<sup>11</sup>. If you have better data available, you can put in new values choosing the last line of the table (line 17) and follow the instructions on the screen.
- Finally, you have to choose a type of combination of secondary measure installed<sup>1</sup>. As mentioned above, you can put in different values of efficiencies and availabilities by choosing one secondary measure from the table (typing the corresponding number). Or else you can put in your own values by selecting the last line of the table (line 6). Please follow the instructions on the screen.

At the end the following message appears on the screen: You can save the data-sheet named 'AINPUSO2.XLS' under a different name.

If you want to do further model runs, just type 'Ctrl'-'a' (or 'Strg'-'a') and the programme starts again.

In order to finish your calculation, just quit EXCEL without saving changes in any of the 19 basic files of this software.

If the tables with the default values are overlapped by a 'question-window' you can move this window: point on the headline of this little window with your mouse-pointer, hold your left mouse-button and move it.

**Annex 15:** Frame conditions of the detailed investigation concerning start-up emissions and start-up emission factors /based on 116/

# **Approach**

Start-ups have to be considered in a boiler-by-boiler approach. In order to determine the relevance of start-up emissions compared to full load emissions, measured emission data for SO<sub>2</sub>, NO<sub>2</sub> and CO obtained from power plant operators have been analysed. Start-up emissions and start-up emission factors have been determined in principle by using the detailed methodology described in Section 5.

#### Technical specifications

The analysis of start-up emissions was accomplished by using measured values from dry bottom boilers, wet bottom boilers and a gas fired boiler. The interpretation of start-up emissions and start-up emission factors should take into account specifications in the design of the boilers and in the configuration of secondary measures installed. In the following, particularities of the boilers considered are given:

- Dry bottom boiler (thermal capacity 1,050 MW and 1,147 MW, hard coal fuelled)

The smaller boiler is equipped with a primary measure for  $NO_x$  reduction (SAS). The SCR is arranged in a high dust configuration (SCR-precipitator-FGD). This boiler is often started slowly and directly connected to the FGD.

The larger boiler is also equipped with a primary measure for  $NO_x$  reduction (SAS). The SCR is also arranged in a high dust configuration (SCR-precipitator-FGD). Due to special arrangements (individual construction of two heat exchangers without any slip between raw and clean flue gas) when this boiler is started up the FGD is by-passed. This boiler is also called "quick" start-up boiler.

- Wet bottom boiler (thermal capacity 499 MW each, hard coal fuelled)

One boiler is equipped with primary measures for  $NO_x$  (like OFA and improved coal mills). The other boiler is not equipped with primary measures. Both boilers are equipped with a common FGD. The SCR is arranged in a tail-end-configuration (precipitator-FGD-SCR) and equipped with a natural gas fired additional furnace. The type of FGD is wet scrubbing (WS). Both boilers are started up directly connected to the FGD.

- Natural gas fired boiler (thermal capacity 1,023 MW)

This boiler is rarely used. It is designed for quick start-ups. As a primary measure, special  $NO_x$  burners are installed. As a secondary measure an SCR is installed.  $SO_x$  abatement is not necessary due to the fact that low sulphur fuels are used.

Boilers without secondary measures show start-up emissions which are below the emissions under full load conditions. During start-ups boilers with secondary measures often show significantly higher SO<sub>2</sub> emissions than during the same time under full load conditions. Start-up emissions are released until the secondary measures are working under optimal conditions (for

SO<sub>2</sub> and NO<sub>2</sub>). CO emissions can be significant up to the time when the boiler operates at minimum load.

The relevance of start-up emissions depends on the following parameters which have to be considered when interpreting measured values (emissions or emission factors):

- the type of boiler (e.g. wet bottom boilers always release higher NO<sub>x</sub> emissions than dry bottom boilers, due to higher combustion temperatures),
- the type of fuel used (e.g. SO<sub>x</sub> emissions are directly related to the sulphur content of the fuel; fuel-nitrogen also contributes to the formation of NO<sub>x</sub>),
- the status of the boiler at starting-time (hot, warm or cold start, see Table 11).
  - the specifications of any individual start-up, like
    - -- the duration and the velocity of the start-up,
    - -- load level obtained (reduced load or full load),
    - -- the configuration of secondary measures (e.g. the start-up time of the high-dust-configurations (SCR-precipitator-FGD) depends on the boiler load, due to the fact that the SCR catalyst is directly heated by the flue gas; tail-end-configurations (precipitator-FGD-SCR) can have shorter start-up times, due to the fact that the SCR catalyst can be preheated by an additional burner),
    - -- start-up of the flue gas desulphurisation directly or in by-pass configuration,
    - -- emission standards which have to be met (boiler-specific emission standards can be set up below the demands of the LCP Directive).

**Annex 16:** List of abbreviations

a Content of ash in coal (wt.-%)

AC Activated Carbon Process

ar As received be Brown coal

BFCB Bubbling Fluidised Bed Combustion

CF<sub>n</sub> Correction factor for month n [ ]
