- 3 – Aperçu méthodologique
- 4 - Fichiers informatiques relatifs au texte, tableaux et figures du rapport.

résumé

summary

Le présent rapport fournit pour la France sur la période 1990 - 1999 les données d'émissions des différentes substances impliquées dans l'accroissement de l'effet de serre retenues au titre de la Convention Cadre sur le Changement du Climat de l'Organisation des Nations Unies. Les substances inventoriées sont les six gaz à effet de serre direct qui constituent le « panier de Kyoto » : dioxyde de carbone (CO_2), méthane (CH_4), oxyde nitreux (N_2O), les deux familles de substances halogénées – hydrofluorocarbures (HFC) et perfluorocarbures (PFC) ainsi que l'hexafluorure de soufre (SF_6). A ces substances s'ajoutent les quatre gaz à effet de serre indirect : SO_2 , NO_x , COVNM et CO pour lesquels les Etats sont invités à rapporter les émissions dans le cadre de la convention.

Pour l'ensemble de la période 1990 – 1998 les estimations produites dans les inventaires précédents ont été revues et corrigées pour tenir compte des mises à jour statistiques, de l'amélioration des connaissances, de modifications méthodologiques et des **spécifications contenues dans le document FCCC/CP/1999/7** de la Convention Cadre sur le Changement Climatique des Nations Unies (UNFCCC) pour ce qui concerne les rapports relatifs aux inventaires d'émissions et notamment la mise en œuvre du format de rapport commun (CRF).

Les **émissions des gaz à effet de serre direct** exprimées en terme de pouvoir de réchauffement global se situent pour l'année 1999 à **2,1 % au-dessous de celles de 1990**. Cette **stabilité apparente** se traduit dans le détail des six gaz impliqués par des **situations beaucoup plus contrastées**. Le niveau d'émission nette de dioxyde de carbone est en 1999 supérieur de 3 % à celui de 1990,

The present report supplies emission data, for France and for the period 1990 - 1999, concerning all the substances involved in the increase in the greenhouse effect and covered under the United Nations' Framework Convention on Climate Change (UNFCCC). The substances are the six direct greenhouse gases covered by the Kyoto protocol : carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), the two species of halogenous substances - hydrofluorocarbons (HFCs) and perfluorocarbons (PFCs), and sulphur hexafluoride (SF_6). Emissions of sulphur dioxide (SO_2), nitrogen oxides (NO_x), non methane volatile organic compounds (NMVOCs), and carbon monoxide (CO), gases which indirectly make a significant contribution to the greenhouse effect, are reported under the Convention.

For the period 1990 - 1998 as a whole, estimates provided in the previous inventories have been reviewed and corrected to take into account updated statistics, improved knowledge, possible changes in methodology and specifications contained in the guidelines (FCCC/CP/1999/7) defined by the UNFCCC on reporting for inventories of emissions, in particular the use of the Common Reporting Format (CRF).

The emissions of the six gases that directly contribute to the greenhouse effect are expressed in terms of Global Warming Potential (GWP) which decreased by 2.1 % in 1999 compared to 1990. This apparent unchanged level of emissions shows, in detail, trends, in each of the six gases involved, that are much more standing in contrast. The level of net CO_2 emissions is higher by 3 % in 1999 than in

les rejets de **méthane** sont en **recul de près de 9 %**, les émissions d'**oxyde nitreux en diminution de 17 %**.

L'inventaire met aussi en évidence une **évolution très atypique** des émissions **des hydrofluorocarbures en masse (+962 %)** qui, compte tenu des **différences structurelles** liées aux molécules mises en jeu, se traduit **seulement par un accroissement de 109 %** en terme de pouvoir de réchauffement global. Les **perfluorocarbures** sont en **régession de 41 %** et l'**hexafluorure de soufre croît de 10 %** sur la période 1990 - 1999. Les émissions de **HFC et de PFC** tendent à **s'accroître rapidement au cours des trois à quatre dernières années**.

Les émissions des gaz à effet de serre indirect sont orientées à la baisse pour les quatre gaz visés. Cette **baisse** est de **17 %** pour les **oxydes d'azote**, **23 %** pour les **composés organiques volatils non méthaniques**, **33 %** pour le **monoxyde de carbone** et atteint **44 %** pour le **dioxyde de soufre**.

La contribution des différents gaz au "panier" est la suivante pour 1999 (en %) : CO₂ 70 ; N₂O 16 ; CH₄ 12 ; SF₆ 0,5 ; HFC 0,99 et PFC 0,39.

Les puits de CO₂ représentent environ un quart des émissions brutes totales de gaz à effet de serre exprimées en équivalent CO₂.

Bien que des progrès significatifs soient introduits en continu quant à la couverture des sources et la qualité des estimations, les émissions s'accompagnent d'incertitudes non négligeables dont il convient de tenir compte dans l'utilisation de ces informations.

Des révisions ultérieures de ces données sont toujours possibles sinon probables pour tenir compte des modifications méthodologiques et des travaux en cours au plan international en vue d'améliorer la connaissance et les règles d'établissement et de présentation des émissions.

1990, emissions of CH₄ are decreasing by 9 %, emissions of N₂O are in decrease by 17 %. The inventory also shows an atypical trend in the emissions of HFCs in mass (+ 962 %), i.e., taking into account structural differences linked to the present molecules, an increase by 109 % only in terms of GWP. PFCs are decreasing by 41 % and SF₆ is increasing by 10 % within the period 1990 - 1999. Emissions of HFCs and PFCs lead to increase swiftly within the three, four last years.

The emissions of the four gases that indirectly contribute to the greenhouse effect are moving towards decrease: this is by 17% for NOx, 23% as regards NMVOCs, 33% for CO and by 44% regarding SO₂.

Out of the six greenhouse gases covered by the Kyoto Protocol, CO₂ accounts for the largest share in total GWP emissions (70 %), followed by N₂O (16 %), CH₄ (12 %), HFCs (0.99 %), SF₆ (0.5 %), and PFCs (0.39 %).

CO₂ sinks account for approximately one quarter of the total crude greenhouse gas emissions expressed as CO₂ equivalent.

Despite the fact that significant progresses have been introduced continuously with regard to the covering of sources and the quality of estimates, emissions have uncertainties that are not negligible and which must be taken into account in the use of this information.

Future reviews of these data are always possible, if not probable, to take into account both changes in methodology and work underway at international level in order to improve knowledge and rules on compiling and presenting emissions.

EMISSIONS DES GAZ A EFFET DE SERRE EN FRANCE (Métropole et Outre-mer)

Ces valeurs sont régulièrement révisées et complétées afin de tenir compte de l'amélioration permanente des connaissances et des méthodes d'estimation. Les utilisateurs sont invités à s'assurer de l'existence de mises à jour plus récentes.

préambule

La convention cadre des Nations unies sur le changement climatique comporte les dispositions relatives à la communication des informations portant sur les émissions dans l'air ; à savoir, les émissions de gaz à effet de serre direct (CO_2 , CH_4 , N_2O , HFC, PFC, SF_6) et à effet indirect (NO_x , CO, COVNM, SO_2). Le Protocole de Kyoto adopté le 10 décembre 1997 précise les engagements assignés à chaque Etat signataire.

Les données présentées s'appliquent aux champs géographiques, temporels et sectoriels définis spécifiquement dans ce cadre et peuvent donc différer de celles correspondant à d'autres définitions établies dans le cadre d'autres conventions comme par exemple celle relative à la pollution transfrontalière à longue distance.

Au cours des dernières années, notamment depuis 1994, date du premier inventaire des émissions de gaz à effet de serre (cf. Programme National de Prévention du Changement de Climat - Février 1995), les estimations des émissions ont été révisées à plusieurs reprises pour tenir compte des événements intervenus au plan international concernant le développement et l'harmonisation des méthodes de quantification des rejets atmosphériques. Ce processus n'est pas encore totalement achevé, ce qui laisse augurer que de nouvelles révisions s'avéreront nécessaires, en particulier en ce qui concerne la comptabilisation des puits de CO_2 . En outre, au plan national, diverses investigations sont régulièrement menées afin d'améliorer la qualité des estimations des émissions. Le présent rapport intègre les changements et progrès effectifs à ce jour. Certaines estimations peuvent donc différer sensiblement de celles produites précédemment.

Ce rapport annule et remplace toutes les publications antérieures établies pour la même application, en particulier les mises à jour de l'inventaire en date du 30 avril 1999 et du 1^{er} mars 2000.

Avec l'amélioration continue des connaissances, les évolutions méthodologiques, les révisions statistiques et les évolutions des spécifications de l'inventaire susceptibles d'intervenir, il y a lieu d'attirer l'attention du lecteur sur la nécessité de s'assurer auprès du CITEPA de l'existence éventuelle d'une mise à jour plus récente.

pour une bonne interprétation des résultats

1. Références et limitations méthodologiques

Les estimations des émissions sont déterminées et rapportées conformément aux prescriptions définies par l'UNFCCC (cf. document FCCC/CP/1999/7 et Guidelines du GIEC publiées en 1996). Plus précisément, les émissions sont estimées selon les méthodes préconisées ou des méthodes équivalentes et les données sont rapportées selon la structure définie dans les tables du format de rapport commun (CRF) établi par les Nations Unies.

Dans le présent inventaire, la France couvre l'ensemble constitué par les 96 départements de la métropole, les départements d'outre-mer (Guadeloupe, Martinique, Guyane et Ile de la Réunion), les collectivités territoriales de Saint-Pierre-et-Miquelon et de Mayotte, ainsi que les territoires d'outre-mer (Nouvelle-Calédonie, Polynésie Française et Wallis-et-Futuna). Quelques autres territoires exiguës et pratiquement inhabités ainsi que les Terres Australes et Antarctiques Françaises ne sont pas pris en compte ; les émissions anthropiques y étant quasi nulles. Cette particularité géographique propre à la France a conduit à réaliser en fait deux inventaires : l'un relatif à la métropole et l'autre relatif aux départements et territoires d'outre-mer.

Les émissions sont déterminées, dans un premier temps, au moyen du système CORINAIR utilisé par le CITEPA pour réaliser l'ensemble des inventaires français. Ce système, reconnu au plan international et largement utilisé à l'échelle européenne, est conçu avec pour objectif de répondre à différents besoins en matière d'inventaire d'émissions (la Convention Climat étant l'un d'eux). Il est basé sur une structure suffisamment fine pour être compatible avec les spécifications de l'UNFCCC. C'est à dire que le niveau de détail des sources prises en compte est, sauf exception, égal ou plus fin que celui requis par le CRF.

Dans un deuxième temps, les résultats obtenus selon la structure fine CORINAIR (SNAP 97) sont traduits au format UNFCCC / CRF par l'intermédiaire d'une interface permettant d'allouer à chaque poste du CRF chacune des émissions élémentaires du système CORINAIR (voir annexe 1). Ces données sont complétées autant que de besoin par des informations additionnelles pour produire l'inventaire selon les spécifications demandées.

Une description générale de la méthode est présentée en annexe 3. Cependant, pour une bonne interprétation des résultats, quelques éléments sont rappelés ci-après.

La méthode utilisée pour les sources liées à l'utilisation de l'énergie, correspond à l'approche dite "sectorielle". Les tests effectués pour le CO₂ conduisent à l'obtention de résultats en bon accord avec l'approche dite de "référence". Toutefois, il est utile de rappeler que les conventions suivantes ont été retenues :

- l'auto-production d'électricité est comptabilisée dans le secteur producteur comme par exemple l'industrie, le chauffage urbain, etc. (spécification GIEC).
- les émissions de COVNM par évaporation dans le cas des véhicules routiers figurent dans la rubrique transports routiers dans la catégorie combustion (spécification UNFCCC).

- la définition du trafic maritime international prise en compte est identique à celle retenue par la Commission Economique pour l'Europe des Nations Unies. De ce fait, une partie des soutes françaises n'est pas comptabilisée dans le champ couvert par les émissions nationales. Cette partie correspond à environ 9 Mt CO₂ en 1999 et 8 Mt en 1990. La partie non comptabilisée dans le total national est rapportée hors total (spécification UNFCCC).
- Le trafic aérien domestique est inclus dans le total national, tandis que la part relative au trafic aérien international est rapportée séparément (spécification UNFCCC). Les quantités correspondantes passent de près de 9 Mt CO₂ en 1990 à 14 Mt CO₂ en 1999.
- les forêts qui ne sont pas dans un état d'équilibre naturel ont été intégrées dans les émissions anthropiques (95 % de la forêt en métropole).
- les émissions de CO₂ d'origine organique lors du traitement des déchets ne sont pas retenues : on conserve seulement 15 % du CO₂ provenant de l'incinération des déchets ménagers (estimation de la part de carbone inorganique) et l'on exclut le CO₂ provenant de l'incinération des boues issues du traitement des eaux, de l'épandage des boues, des décharges, de la fabrication de compost et de la production de biogaz.

2. Pouvoir de réchauffement global et définitions

Le pouvoir de réchauffement global net (PRG), intégré sur une période de 100 ans, provenant des six substances retenues dans le protocole de Kyoto est calculé au moyen des PRG respectifs de chacune des substances exprimés en équivalent CO₂. A savoir :

$$\text{PRG}_{\text{CO}_2} = 1 \text{ par définition}$$

$$\text{PRG}_{\text{CH}_4} = 21$$

$$\text{PRG}_{\text{N}_2\text{O}} = 310$$

$$\text{PRG}_{\text{SF}_6} = 23900$$

PRG_{HFC} = valeurs variables selon les molécules considérées et leurs contributions qui sont variables au cours des années de la période étudiée (exemples 8733 en 1990, 1673 en 1998). Les calculs sont effectués sur les bases suivantes : HFC-125 = 2800, HFC-134a = 1300, HFC-143a = 3800, HFC-152a = 140, HFC-227ea = 2900, HFC-23 = 11700, HFC-4310mee = 1300 et HFC-32 = 650.

PRG_{PFC} = valeurs variables selon les molécules considérées et leurs contributions qui sont variables au cours des années de la période étudiée (exemples 7075 en 1990, 7173 en 1998). Les calculs sont effectués sur les bases suivantes : PFC-14 = 6500, PFC-116 = 9200, C₄F₁₀ = 7000, C₅F₁₂ = 7500, C₆F₁₄ = 6500.

Les émissions des différentes substances rapportées sous entendent les définitions suivantes :

- CO₂ dioxyde de carbone exprimé en CO₂ ultime, soit brut, soit net. Dans ce dernier cas les puits sont déduits des émissions brutes.
- CH₄ méthane exprimé en CH₄.
- N₂O oxyde nitreux exprimé en N₂O.
- HFC hydrofluorocarbures exprimés en somme de HFC bruts (aucune équivalence n'est prise en compte sauf pour le calcul du PRG).
- PFC perfluorocarbures exprimés en somme de PFC bruts (aucune équivalence n'est prise en compte sauf pour le calcul du PRG).
- SF₆ hexafluorure de soufre exprimé en SF₆.

Les quatre gaz ci-dessous participent indirectement à l'accroissement de l'effet de serre en tant que polluants primaires intervenant dans la formation de polluants secondaires gazeux contribuant à l'effet de serre comme l'ozone ou les aérosols. Ils n'entrent pas dans le "panier" de Kyoto et ne sont pas assortis d'un PRG par les experts du GIEC. Ils sont inclus dans l'inventaire avec les conventions suivantes :

- CO monoxyde de carbone exprimé en CO.
- COVNM composés organiques volatils non méthaniques exprimés en somme de COV bruts (aucune équivalence n'est prise en compte).
- NOx NO + NO₂, exprimés en équivalent NO₂.
- SO₂ SO₂ + SO₃, exprimés en équivalent SO₂.

3. Facteurs d'émission

Les facteurs d'émission retenus sont déterminés pour chaque type de source, de combustible et de technique rencontrés. Ils tiennent compte dans un grand nombre de cas de données spécifiques relatives à chaque secteur et/ou au cas français. Un certain nombre de données proviennent d'une mesure directe des émissions en particulier pour le SO₂ et secondairement les NOx, les COVNM et le N₂O.

Dans le cas particulier du CO₂ résultant de la combustion d'énergie fossile, des facteurs d'émission sont utilisés par défaut lorsque des informations spécifiques ne sont pas disponibles. A savoir pour les principaux combustibles (en kg CO₂/GJ) :

charbon à coke ou à vapeur	95	charbon sous-bitumineux	96
agglomérés	95	lignite	100
coke de houille	107	coke de lignite	108
coke de pétrole	96	fioul lourd	78 +/- 1 selon qualité
fioul domestique et gazole	75	kérosène et carburéacteur	74
essence	73	gaz naturel	57
GPL	64	gaz de raffinerie	56
gaz de cokerie	47	gaz de haut fourneau	268

Pour les autres sources, non relatives à l'utilisation de l'énergie, les facteurs d'émission sont, si nécessaire, déterminés au cas par cas.

4. Principales modifications apportées à la présente révision

Depuis la mise à jour de l'inventaire des émissions de gaz à effet de serre en date du 1^{er} mars 2000, plusieurs améliorations et changements notables ont été opérés. Les corrections concernent dans certains cas toute la série chronologique et dans d'autres cas n'affectent que certaines années. Les principaux écarts enregistrés sont explicités ci-après ; on se limite aux bornes de l'intervalle considéré dans le rapport précédent (années 1990 et 1998). Les différences dues aux ajustements des données provisoires utilisées précédemment en raison de l'indisponibilité de certaines informations ne sont pas détaillées car implicites.

Le détail des modifications est indiqué dans les tables correspondantes du CRF pour l'année 1999.

4.1 - Energie

- la révision statistique rétroactive du bilan énergétique apportée par l'Observatoire de l'Energie aux années 1996 à 1998 conduit à une révision des valeurs précédentes.
- la consolidation de l'enquête chauffage urbain pour 1997 a induit une mise à jour des données qui reste limitée. A noter que les enquêtes pour 1998 et 1999 n'étant pas encore disponibles, les valeurs de 1997 ont été provisoirement reportées et feront l'objet d'ajus-

tements ultérieurs. Par effet de ricochet, toute modification du poste "chauffage urbain" a une incidence sur le secteur "résidentiel / tertiaire / commercial" du fait de la structure du bilan énergétique national.

- les consommations de produits combustibles issus de la biomasse (bois et résidus de récoltes) ont été entièrement révisés suite à la disponibilité de l'étude réalisée par le CEREN pour l'Observatoire de l'Energie. Les secteurs "industrie" et "résidentiel / tertiaire / commercial" sont concernés. Pour le secteur "résidentiel", le résultat de cette révision se traduit par une augmentation des émissions de l'ordre de 12 % en 1990 (soit 6 Tg pour le CO₂). Cet écart s'amenuise au cours des années suivantes pour être quasi nul en 1997.
- les travaux dits de " rebasement de la circulation " effectués dans le courant de l'année par la Commission des Comptes des Transports de la Nation (CCTN) ont conduit à une révision des hypothèses du parc roulant et des consommations de carburants. Par effet de ricochet, ces nouvelles hypothèses affectent également le trafic maritime (voir plus loin). Les émissions du transport routier pour CO₂ et SO₂, substances liées uniquement aux quantités consommées, ne subissent que des changements relativement faibles, tandis qu'ils sont plus importants pour les autres substances qui dépendent du type de véhicule et des conditions de circulation. Le CO₂ est diminué de respectivement 2,1 et 1,7 Tg en 1990 et 1998, le SO₂ baisse de 4 et 0,55 Gg, les NOx augmentent de 7 et 20 Gg, les COVNM reculent de 65 et 67 Gg et le CO baisse de 48 et 148 Gg.
- les apports du groupe de travail de la DGAC sur l'évaluation du CO₂ du trafic aérien a conduit à un nouvel affinement en tenant compte notamment des appareils de type turbo-propulseur. Une surestimation des émissions du trafic national dans la version précédente a été mise en évidence. Les émissions de CO₂ sont réduites respectivement de 0,76 et 1,3 Tg en 1990 et 1998, celles de NOx sont diminuées de 10 et 5 Gg. Les modifications concernent aussi SO₂, CO et COVNM mais sont relativement faibles.
- la prise en compte des dispositions dites "stage 1" en ce qui concerne la distribution de l'essence ont été introduites et ont pour conséquence une réduction des émissions de COVNM en 1997 (-0,5 Gg) et en 1998 (-7,4 Gg).
- la conséquence des travaux de la CCTN déjà mentionnés ci-dessus et la révision des facteurs d'émission du SO₂ pour le trafic maritime ont un impact important sur le SO₂ (+10 Gg en 1990 et +9,4 Gg en 1998), les NOx (+4,2 Gg en 1990 et +1,8 Gg en 1998), les COVNM (+21 Gg en 1990 et +30 Gg en 1998), le CO (+85 Gg en 1990 et +123 Gg en 1998) et le CO₂ (+0,7 Tg en 1990 et 0,6 Tg en 1998)

En conséquence, les consommations d'énergie des secteurs 1A1, 1A2, 1A3, 1A4 et 1B2 ont été révisées.

4.2 - Procédés industriels

Les études relatives aux gaz fluorés (HFC, PFC et SF₆) se sont poursuivies notamment en ce qui concerne les HFC avec les travaux de D. Clodic de l'Ecole des Mines de Paris et divers autres secteurs. Elles ont permis d'affiner certaines informations. Le domaine du froid est particulièrement concerné. Au total les émissions de l'année 1998 sont relevées de 226 Mg pour les HFC, et de 7 Mg pour les PFC. D'autres années intermédiaires ont également fait l'objet de modifications.

4.3 - Solvants et autres produits

- l'application stricte des règles du CRF ont conduit à ne plus convertir en CO₂ la quantité de carbone contenue dans les COVNM attribués au secteur 3C. L'impact sur les émissions de CO₂ reste très faible (de l'ordre de 0,3 Tg).

-
- certaines entreprises appartenant au secteur de la chimie fine ont été nouvellement prises en compte, ce qui amène une réévaluation des émissions de COVNM de 6,5 Gg en 1990 et de 4,3 Gg en 1998.

4.4 - Agriculture

Il n'y a pas de changement apporté dans ce secteur depuis la dernière version de l'inventaire, mis à part des ajustements statistiques de données devenues disponibles dans l'intervalle.

4.5 – Changement d'affectation des sols et sylviculture

- il n'y a pas eu de changement apporté dans ce secteur depuis la dernière version de l'inventaire, mis à part des ajustements statistiques de données devenues disponibles dans l'intervalle.
- la mise à jour des profils de température utilisés pour l'année 1998 est responsable d'une correction de -20 Gg de COVNM.

4.6 – Déchets

- c'est dans le domaine du traitement des déchets qu'est intervenue la principale modification depuis la révision précédente de l'inventaire en mars 2000. Du fait de la disponibilité de données plus nombreuses et plus détaillées issues des enquêtes de l'ADEME, il s'avérait judicieux de réviser les estimations précédentes. Jusqu'à la version de mars 2000, les émissions des décharges d'ordures ménagères et assimilées étaient déterminées au moyen de la méthode dite "d'ordre zéro" (la totalité des déchets est supposée se décomposer durant l'année de mise en décharge). La révision méthodologique consiste à utiliser la méthode préconisée par le GIEC dite "d'ordre un" (les déchets sont supposés se décomposer progressivement pendant 30 ans avec une loi de décroissance préétablie) plus représentative de la réalité du phénomène. Les deux méthodes aboutissent à terme aux mêmes quantités de gaz de décharge, mais diffèrent sur leur répartition dans le temps. La nouvelle méthode et les paramètres associés ont été mis en œuvre en concertation avec l'ADEME. Les changements introduits conduisent à rectifier les émissions de CH₄ de +73 Gg en 1990 et +364 Gg en 1998.
- le retour des informations issues de la TGAP en ce qui concerne l'incinération des déchets ménagers a permis d'affiner les facteurs d'émission précédemment utilisés à partir de l'année 1995. Cette modification concerne le SO₂, les NOx et les COVNM et représente -8 Gg en 1998 pour le SO₂, -12 Gg pour les NOx et -0,8 Gg pour les COVNM.

4.7 – Autre

Ce secteur ne reçoit toujours aucune source émettrice.

4.8 – Memo items

Les travaux mentionnés en ce qui concerne le trafic aérien (cf. section 4.1 ci-dessus) ont également un impact sur les quantités d'émissions rapportées hors total national pour les avions. Le CO₂ est ajusté à la hausse de 0,77 Tg en 1990 et de 0,78 Tg en 1998, les NOx sont abaissés de 3,9 et 1,2 Gg respectivement aux années 1990 et 1998. Le CO, les COVNM et le SO₂ sont affectés de manière marginale.

résultats

Les résultats d'ensemble pour les années 1990 à 1999, pour la France (Métropole et outre-mer) comportent les émissions brutes de chaque gaz à effet de serre et le pouvoir de réchauffement global. Les émissions de HFC et de PFC sont fournies pour chacune des molécules concernées.

1. Emissions par substance et Pouvoir de Réchauffement Global (PRG)

Le tableau page 16 présente les émissions des six gaz à effet de serre direct, des quatre gaz à effet de serre indirect ainsi que le PRG pour la France (Métropole et outre-mer) au cours de la période 1990 - 1999.

De l'examen de ces résultats, il découle :

1.1 - CO₂

Les émissions brutes de CO₂ sont en augmentation de près de 6 % sur la période 1990 - 1999, mais compte tenu de l'évolution des puits, les émissions nettes de CO₂ de 1999 ne sont supérieures à celles de 1990 que de seulement 3 %. La forte corrélation des rejets de CO₂ et de la consommation d'énergie fossile rend sensible le fait que les émissions sont estimées sur la base de données non corrigées des variations climatiques. La comparaison des années 1990 et 1999 doit être doublement appréciée compte tenu que cette dernière année a été au plan climatique nettement moins douce comparativement à 1990 (voir ci-dessous). Si l'on s'affranchit de l'incidence de la variabilité climatique, les émissions au cours de l'année 1999 seraient donc plus proches de celles de 1990. Les niveaux plus élevés observés en 1991 et 1998 par rapport au reste de la décennie s'expliquent en grande partie par des circonstances climatiques ou conjoncturelles particulières (sollicitation accrue des centrales thermiques classiques de production d'électricité, activité économique plus soutenue, etc.).

Coefficients de rigueur (la valeur 1 correspond à la moyenne trentenaire 1961 - 1990)

1990	1991	1992	1993	1994	1995	1996	1997	1998	1999
0,88	1,05	0,96	0,97	0,85	0,93	1,03	0,90	0,96	0,93

Les puits de CO₂ dus à la photosynthèse et aux variations de la teneur en carbone du sol (160 Tg en 1999) représentent environ 30 % des émissions totales de CO₂ et sont en légère hausse continue au cours de la période (un peu plus de 1 % par an en moyenne).

1.2 - CH₄

Après avoir atteint un point haut en 1995, les émissions de CH₄ sont depuis cette date en diminution notable de 13 % en quatre ans, ce qui conduit à une baisse des émissions de près de 9 % par rapport à 1990. Cette évolution est due à la captation des gaz de décharge.

1.3 - N_2O

Jusqu'en 1997 les émissions de N_2O fluctuaient avec une amplitude de quelques pour-cent autour d'une valeur moyenne d'environ 295 Gg. Au cours des deux dernières années une nette diminution est observée en raison principalement des actions menées dans le secteur des industries chimiques. L'écart est de -17 % en 1999 par rapport à 1990.

1.4 - HFC

Les rejets de HFC sont caractérisés par un accroissement très fort de la quantité émise en masse entre 1990 et 1999 par suite de l'utilisation de ces produits en substitution aux CFC (+ 962 %). Toutefois, l'effet de structure des différentes molécules émises conduit à un accroissement plus limité du PRG relatif aux HFC (+ 114 %).

Les émissions brutes de HFC sont en très nette augmentation ces dernières années, en particulier en raison du développement de l'utilisation de ces produits dans la réfrigération (climatisation automobile entre autres) et dans les aérosols en remplacement des CFC interdits par le protocole de Montréal. En revanche, les émissions fugitives lors de la production sont beaucoup mieux contrôlées depuis 1990 et diminuent à partir de 1992.

Les émissions de HFC, exprimées en CO_2 équivalent, diminuent entre 1990 et 1994 et restent inférieures au niveau de 1990 jusqu'en 1995. Ce recul provient de la forte évolution structurelle des types de HFC émis depuis 1990. A cette date le HFC-23, sous-produit de la fabrication du HCFC-22, était le principal composé émis à l'atmosphère avec un coefficient de 11 700 en équivalent CO_2 (PRG à 100 ans). Au cours des années suivantes, le HCFC-22 est progressivement abandonné. Dans le même temps, le HFC-134a (coefficient de 1300 en équivalent CO_2), est de plus en plus utilisé à partir de 1993. Ceci explique que les émissions de HFC, traduites en équivalent CO_2 , ne retrouvent leur niveau de 1990 qu'à partir de 1996 bien qu'en terme d'émissions brutes, les émissions soient très fortement orientées à la hausse à partir de 1993. Cet accroissement se poursuit à un rythme soutenu en 1997, 1998 et 1999.

1.5 - PFC

Les PFC voient leurs émissions brutes réduites de 40 % au cours de la période 1990 - 1999.

Les émissions brutes de PFC sont en régression jusqu'en 1995 (meilleur contrôle des émissions du PFC-14 et du PFC-116 lors de la production d'aluminium par électrolyse) puis repartent à la hausse du fait d'une utilisation accrue de ces produits dans l'industrie électronique et d'une recrudescence des émissions de l'électrolyse de l'aluminium.

Les effets de structure sont moins importants dans le cas des PFC car les PRG des différentes molécules sont plus proches (entre 5100 et 9200 équivalent CO_2). De plus, les variations des émissions brutes de chaque PFC ne sont pas aussi importantes que dans le cas des HFC. Par suite, les quantités de PFC exprimées en équivalent CO_2 , diminuent entre 1990 et 1999 dans une proportion similaire à celle des émissions en masse brute, soit de 40 %.

1.6 - SF_6

Les émissions de SF_6 sont en hausse lente mais régulière d'environ 2 % par an jusqu'en 1997. En 1998 et 1999, une légère baisse est enregistrée du fait de la réduction de l'utilisation de ce composé dans la fabrication des microprocesseurs et de certaines chaussures de sport, compensée par une hausse liée à une production plus importante d'équipements électriques. La situation observée en 1999 fait apparaître un accroissement de 10 % par rapport à 1990.

Les usages principaux du SF₆ concernent les équipements électriques, la production de métaux et l'industrie électronique. La répartition sectorielle des émissions varie peu au cours des années.

1.7 - PRG

Les variations des rejets des six gaz ci-dessus se traduisent globalement par un écart de -2,1 % du PRG en 1999 comparé au niveau de 1990. Une réduction plus notable est observée lorsque le PRG est rapporté à la population (-6 %) ou au Produit Intérieur Brut (-28 %). Cette stabilité du PRG résulte des évolutions respectives des différents gaz : les réductions du CH₄, du N₂O et des PFC compensent à peu près les accroissements du CO₂ du SF₆ et des HFC.

1.8 - SO₂, NOx, COVNM et CO

Les quatre gaz à effet de serre indirect étudiés voient leurs émissions orientées à la baisse au cours des neuf années écoulées (-46 % pour le SO₂ , -33 % pour le CO, -23 % pour les COVNM et -17 % pour les NOx).

Le rejet d'environ 740 kt de SO₂ en 1999 constitue le plus bas niveau atteint depuis plus de un demi siècle et confirme la forte tendance de diminution entamée en 1991 et qui avait été interrompue en 1998 en raison de circonstances particulières. Cette tendance est à mettre principalement à l'actif de la réduction de la teneur en soufre des combustibles pétroliers et à la part de plus en plus prépondérante prise par des combustibles peu soufrés.

Les émissions de NOx continuent à décroître principalement en raison de la pénétration accrue des pots catalytiques sur les véhicules routiers.

La même cause contribue à la baisse des rejets de COVNM, mais celle-ci est également due à des progrès significatifs dans le domaine de la distribution des carburants et dans l'utilisation des solvants.

La forte baisse du CO provient aussi de l'équipement des véhicules en pots catalytiques, mais aussi de progrès dans le domaine de l'industrie notamment la sidérurgie.

(a) puits, changement d'utilisation des sols et sylviculture inclus

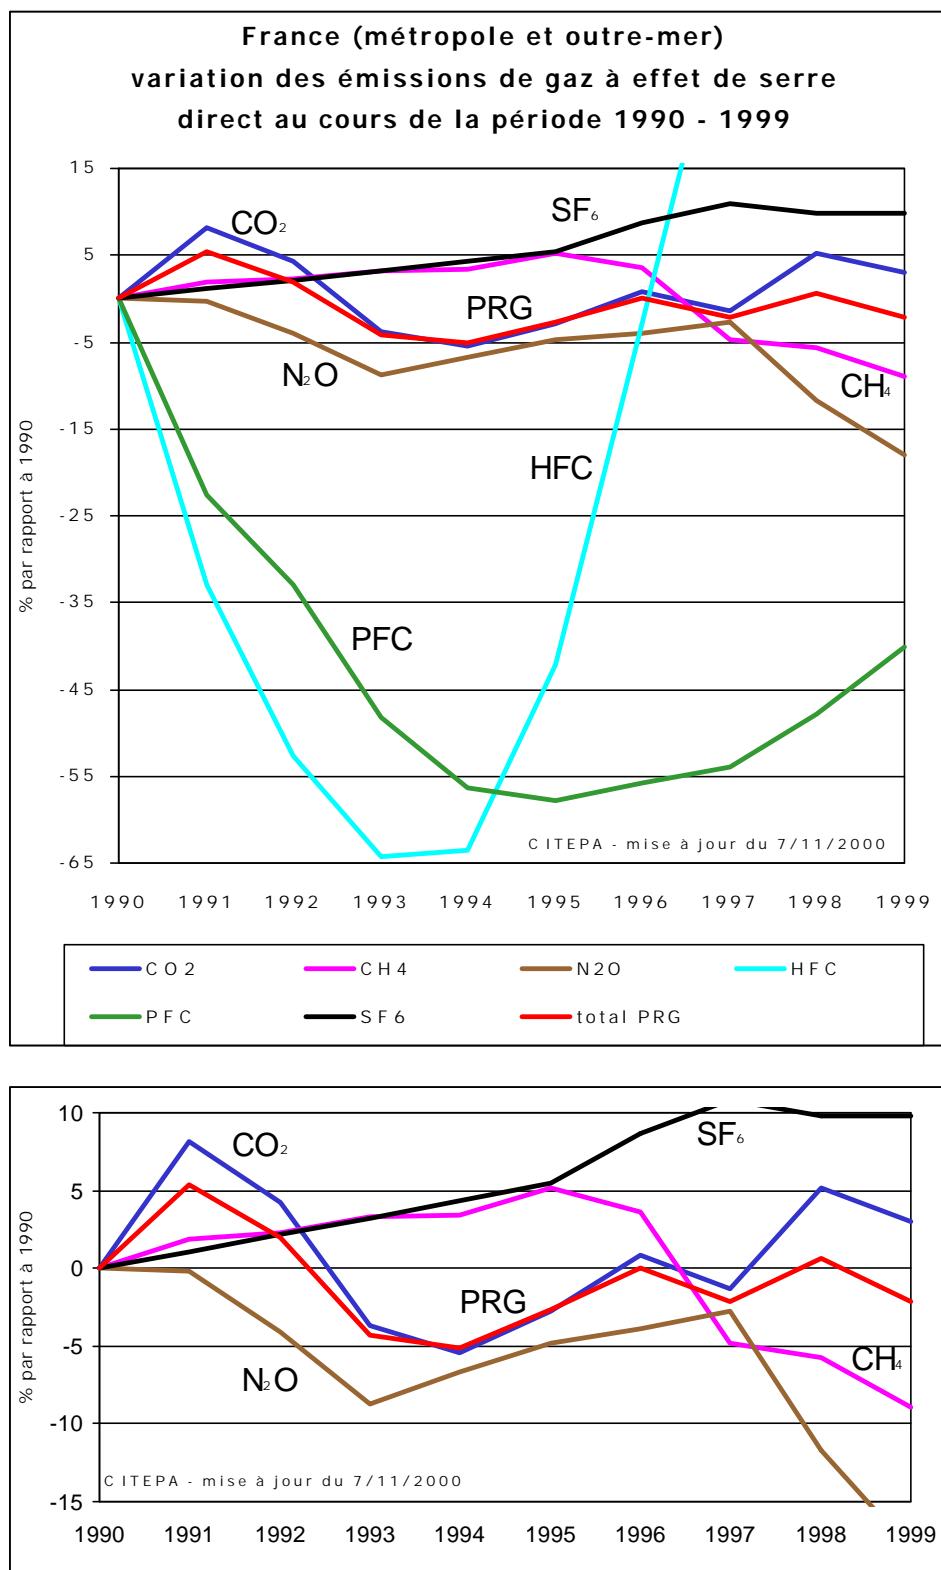

(c) hors changement d'utilisation des sols, hors puits et hors sylviculture

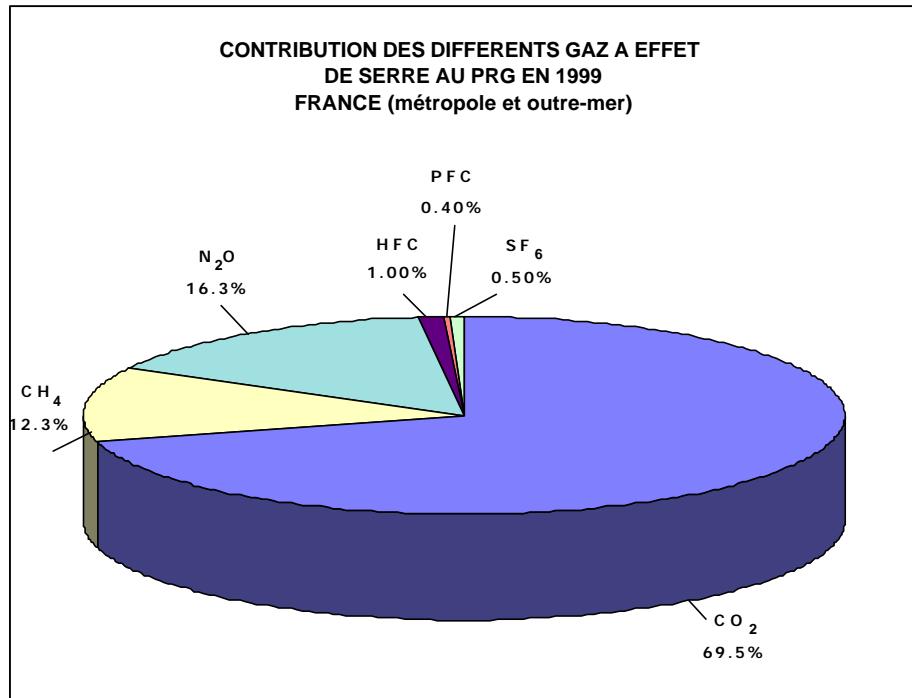

(b) pour le changement d'utilisation des sols et superficies mises à l'abri, et (c) pour le réchauffement global intégré sur une période de 100 ans et calculé sur la base des coefficients suivants :

$\text{CO}_2 = 1$; $\text{CH}_4 = 21$; $\text{N}_2\text{O} = 310$; $\text{SF}_6 = 23900$; HFC et PFC = valeurs variables dépendantes de la part relative des différentes molécules.

(*) Les émissions du trafic maritime international et du trafic aérien international sont exclues.

(**) Tq équivalent Carbone = (12/44) Tq équivalent CO₂

2. Particularités métropole et outre-mer

Au vu de la part relativement limitée que représente l'outre-mer, les résultats d'ensemble s'appliquent à peu de chose près à la métropole pour laquelle les résultats sont présentés dans le premier tableau ci-après. On notera cependant que, concernant le CO₂, les émissions brutes localisées outre-mer sont en nette augmentation au cours de la période étudiée. L'évolution des émissions nettes est très peu précise compte tenu de la méconnaissance des puits dans ces territoires (une valeur forfaitaire unique est prise pour les puits pour toutes les années). Cet accroissement est lié à une augmentation soutenue de la consommation d'énergie fossile qui est en adéquation avec l'augmentation importante des rejets de SO₂ et de NOx. On observe une baisse des émissions de ces polluants au cours des deux dernières années par suite des teneurs en soufre réduites des carburants et la pénétration progressive de véhicules munis de pots catalytiques. L'outre-mer participe pour une part modeste au total national : les scores les plus élevés pour l'année 1999 sont ceux du SO₂ (7,8 %), des COVNM (5,2 %) et des NOx (4,5 %). Le CO₂ brut atteint 2,4 % et le CO₂ net 1,8 %. On constatera également la différence de valeur du ratio PRG/habitant entre la métropole et l'outre-mer qui, même s'il se réduit progressivement, est encore d'un facteur supérieur à deux en 1999.

3 Validation et incertitudes

L'évaluation des incertitudes et la validation des résultats de l'inventaire sont des sujets particulièrement complexes. Dans la plupart des cas il est très difficile de déterminer l'incertitude associée à une source donnée compte tenu de la complexité des phénomènes étudiés, de leur variabilité et des méthodes utilisées.

Ces questions ont fait l'objet de travaux dans le cadre du GIEC en vue de réduire ces incertitudes et en tout état de cause de les quantifier en suivant des règles de bonnes pratiques. Ces dernières sont en cours d'approbation.

Afin de s'assurer que l'inventaire propose les meilleures données possibles, l'estimation est produite dans un esprit de démarche assurance qualité qui permet le cas échéant d'expliquer tout le cheminement effectué et les hypothèses prises en compte. Dans nombre de cas, ces éléments sont soumis à l'avis d'experts spécialistes des secteurs considérés.

Des tentatives de recouplements peuvent être effectuées quand cela est possible en particulier en ce qui concerne l'énergie et les produits fluorés en comparant les méthodes "sectorielles" aux méthodes de "référence" (pour l'énergie) et "potentielle" (pour les produits fluorés). Ces méthodes globales alternatives ont leurs propres limites et ne sauraient constituer des référentiels absolu. L'approche "potentielle" s'avère peu pertinente et n'est pas mise en œuvre. L'approche de "référence" pour l'énergie fournit des résultats voisins de l'approche "sectorielle" (voir tableaux ci-après et CRF en annexe). On constate toutefois, que l'application de l'approche de référence détaillée soulève quelques difficultés qui rendent plus incertaines les comparaisons pour des sous-ensembles, tandis qu'au niveau global ces aspects disparaissent.

Par suite les approximations sur le SO₂ et le CO₂ provenant de l'utilisation de l'énergie sont d'une manière générale inférieures à 5 %. Plus précisément concernant le CO₂, la méthode alternative proposée par le GIEC dite "approche de référence" (à partir des bilans énergétiques établis par l'Observatoire de l'Energie) comparée à l'approche sectorielle retenue dans le présent inventaire, conduit à des différences très faibles de l'ordre de 1.5 % au plus (valeur jugée très satisfaisante par le GIEC et l'UNFCCC lorsqu'elle n'excède pas 2 %). Ces écarts s'expliquent par les différences entre les PCI réels et par défaut, les caractéristiques des combustibles et les recouplements statistiques. Pour les autres substances et le CO₂ globalement, les incertitudes sont certainement plus importantes mais ne peuvent pas faire actuellement l'objet d'estimations précises. Des travaux sont en cours tant au plan international que français pour permettre à terme une telle estimation.

L'inventaire national fait en outre l'objet d'une revue de la part des autorités et les différentes administrations concernées sont consultées. Le présent rapport a été approuvé le 6 décembre 2000.

COMPARAISON DE L'APPROCHE DE REFERENCE SIMPLIFIEE ET DE L'APPROCHE SECTORIELLE POUR LES EMISSIONS DE CO₂ DU SECTEUR GIEC ENERGIE (METROPOLE)

Ces valeurs sont régulièrement révisées et complétées afin de tenir compte de l'amélioration permanente des connaissances et des méthodes d'estimation. Les utilisateurs sont invités à s'assurer de l'existence de mises à jour plus récentes.

⁽¹⁾ source bilan énergétique de l'Observatoire de l'énergie (consommation finale énergétique et non énergétique non corrigée du climat)⁽²⁾ source GIEC 1996⁽³⁾ source bilan énergétique de l'Observatoire de l'énergie (quantité de carbone contenu dans les combustibles consommés à des fins non énergétiques = consommation finale non énergétique x carbone contenu x 42)⁽⁴⁾ en considérant que tout le carbone est oxydé comme il est supposé dans l'approche sectorielle

4 Analyse sectorielle

Le premier tableau ci-après présente les contributions les plus importantes aux émissions de chacun des gaz étudiés en considérant les catégories de sources définies par l'UNFCCC.

Les tableaux suivants récapitulent les émissions selon le format UNFCCC pour CO₂, CH₄, N₂O, SO₂, NOx, COVNM et CO.

CONTRIBUTION DES TYPES DE SOURCES AUX EMISSIONS DE GAZ A EFFET DE SERRE FRANCE 1999 (métropole et outre-mer)

La définition des types de sources et l'indication entre parenthèses font référence à la classification du UNFCCC.

4.1 – Energie (secteur 1)

L'utilisation de l'énergie représente chaque année un peu plus de 76 % des émissions de CO₂ brutes et même près de 90 % si l'on y ajoute la biomasse. Ce niveau se situe dans le bas de la fourchette si l'on s'intéresse à la plupart des pays développés du fait de la part importante d'énergie nucléaire.

Cette catégorie est également largement prépondérante vis à vis des émissions de gaz à effet de serre indirect comme le SO₂ (96 %), les NOx (98 %), le CO (83 %) et à un degré moindre les COVNM (43 %) en 1999.

A l'inverse, cette catégorie contribue peu ou pas aux émissions des autres substances étudiées (CH₄, N₂O, HFC, PFC et SF₆).

Le secteur des transports et principalement le transport routier ressort nettement quant aux émissions de CO₂ devant le secteur "résidentiel / tertiaire / commercial / institutionnel", l'industrie manufacturière et les industries de l'énergie. Le même trio, parfois dans un ordre différent, se retrouve bien placé quant aux émissions de NOx et de CO bien que la pénétration accrue des pots catalytiques et de véhicules moins polluants réduise progressivement la part des transports routiers depuis quelques années. La transformation d'énergie précède largement ces trois secteurs en ce qui concerne les rejets de SO₂. Les émissions de CH₄ (extraction du charbon, distribution du gaz naturel) et les émissions de COVNM (stockage, évaporation) sont principalement des émissions diffuses.

Le secteur de la production d'électricité connaît des fluctuations significatives au cours de la période 1990 – 1999 consécutives aux conditions particulières rencontrées chaque année (conditions climatiques, disponibilité des centrales nucléaires et hydroélectriques).

Les émissions de CO₂ du transport routier sont en forte augmentation (+ 16 % entre 1990 et 1999) ce qui n'est pas le cas des autres substances (N₂O excepté) compte tenu des actions réductrices mises en œuvre.

4.2 – Procédés industriels (secteur 2)

Les émissions notables dans cette catégorie concernent le N₂O (16 % des émissions totales en 1999 en équivalent CO₂ contre 19 % en 1990) qui provient en grande partie des productions des acides nitrique, adipique et glyoxylique.

Les procédés industriels regroupent également les sources de HFC, de PFC et de SF₆ qui sont commentées dans les sections 1.4 à 1.6 de la section « Résultats » du présent rapport.

En ce qui concerne les gaz à effet de serre indirect, il est à noter que les parts relatives les plus importantes dans les émissions en 1999 sont pour CO : 11 % (sidérurgie), pour NOx : 0,3 % (acide nitrique), pour COVNM : 1,4 % (agro-alimentaire et chimie organique) et pour SO₂ : 2 % (production d'acide sulfurique).

Ces émissions sont dans l'ensemble orientées à la baisse au cours de la période étudiée.

4.3 – Utilisation des solvants et autres produits (secteur 3)

Cette catégorie concerne principalement les émissions de COVNM provenant de l'utilisation de solvants lors de l'application de peinture, du traitement de surface, etc.

Les émissions de CO₂ traduisent la transformation du carbone contenu dans les émissions de COVNM en CO₂ ultime. Cette conversion appliquée à tous les sous-secteurs à l'exception du sous-secteur 3C (fabrication et mise en œuvre de produits chimiques) se fait sur la base d'un contenu moyen en carbone de 85 %.

4.4 – Agriculture (secteur 4)

L'agriculture est le secteur prépondérant quant aux émissions de CH₄ et de N₂O (respectivement 54 % et 69 % des émissions nationales pour ces deux polluants en 1999).

La fermentation entérique (87 %) et les excréptions animales (11 %) constituent l'essentiel des sources émettrices de CH₄ de cette catégorie.

Les sols imputent pour 94 % dans les émissions agricoles de N₂O. Ces émissions proviennent pour une très large part de l'épandage des engrains minéraux et des déjections animales. Le solde provient essentiellement du stockage des déjections animales. Ces émissions évoluent peu sur la période étudiée. En ce qui concerne le CO₂, les sols agricoles sont traités dans le secteur 5 de l'UNFCCC (voir ci-dessous).

Enfin, les cultures sont émettrices de COVNM pour 20 Gg en 1999.

4.5 – Changement d'utilisation des sols et sylviculture (secteur 5)

L'accroissement de la biomasse (en forêts et hors forêts) et la récolte forestière sont les postes prépondérants dans le calcul des puits et des émissions de CO₂ des changements d'utilisation des sols et de la sylviculture.

L'accroissement de la biomasse entraîne un stockage de CO₂ qui varie de 141 Tg en 1990 à 155 Tg en 1999. Dans le même temps, l'estimation des émissions de CO₂ provenant de la récolte forestière est de 70 Tg en 1999 contre 66 Tg en 1990. Ainsi, le puits résultant s'est accru de 14 Tg de CO₂ entre 1990 et 1999.

Pour sa part, le défrichement forestier (partie du bois de feu non comptabilisé dans la récolte forestière) induit un déstockage de CO₂ qui varie de 11,7 Tg en 1990 à 11,9 Tg en 1999.

Les changements d'utilisation des sols impliquent à la fois un déstockage de CO₂ (conversion des forêts et des prairies en terres agricoles) et un stockage de CO₂ (conversion des prairies et terres agricoles en forêts ainsi que des prairies en terres agricoles non cultivées). De ces deux phénomènes antagonistes résulte une émission de 3,4 Tg de CO₂ en 1999 contre 4 Tg en 1990.

Au bilan, les changements d'affectation des sols et la sylviculture conduisent à un puits de CO₂ qui augmente de plus de 14 Tg de CO₂ entre 1990 et 1999 (respectivement 146 et 160 Tg de CO₂).

4.6 – Déchets (secteur 6)

Le traitement des déchets ne représente au plus que 1 à 2 % des émissions de SO₂, de NOx, de COVNM, de CO₂ et de N₂O.

La mise en décharge est la principale source de CH₄ de cette catégorie qui est la plus importante après l'agriculture (28 % des émissions totales de CH₄ en 1999).

Les émissions de CH₄ ont chuté entre 1990 et 1999 (- 8 % sur la période) par suite du développement de la récupération du gaz de décharge et des actions engagées pour réduire les quantités de déchets mis en décharge.

Les émissions de CO provenant de l'incinération ne représentent qu'une petite part des émissions totales (entre 2,5 et 4 %).

4.7 – Autres sources (secteur 7)

Aucune source n'est rapportée dans cette catégorie, toutes les sources ayant été assignées aussi spécifiquement que possible.

4.8 – Emissions hors total national (memo items)

Cette catégorie regroupe les émissions des sources définies hors du champ « national » dans le cadre de la convention et, pour mémoire, le CO₂ issu de la biomasse qui est comptabilisé implicitement dans le secteur 5.

La section 1 du chapitre « pour une bonne interprétation des résultats » précise les particularités de l'estimation du trafic maritime international.

Les trafics internationaux aériens et maritimes relatifs aux quantités de combustibles vendus en France représentent des émissions « internationales » non négligeables en ce qui concerne plusieurs des substances inventoriées.

Comparées aux émissions nationales, les quantités regroupées dans cet ensemble représentent 6 % pour le CO₂, 13 % pour les NOx, 4 % pour les COVNM et 22 % pour le SO₂ en 1999.

Les tendances au cours de la période 1990 – 1999 semblent être orientées à la hausse en ce qui concerne le CO₂, les NOx, le SO₂ et les COVNM, et stables pour le CO.

acronymes et abréviations

CFC	Chlorofluorocarbures
CITEPA	Centre Interprofessionnel Technique d'Etudes de la Pollution Atmosphérique
CORALIE	COoRdination de la RéALisation des Inventaires d'Emissions
CORINAIR	CORE INventory or AIR emissions
COVNM	Composés Organiques Volatils Non Méthaniques
DOM	Département d'Outre-Mer
Gg	1 Gg (Gigagramme) = 1 000 Mg = 1 kt = 1 000 t
GIC	Grandes Installations de Combustion
GIEC	Groupe Intergouvernemental sur l'Evolution du Climat
HCFC	Hydrochlorofluorocarbures
HFC	Hydrofluorocarbures
Mg	1 Mg (Megagramme) = 1 t (tonne)
NEC	National Emission Ceiling / Plafond d'Emission National
PFC	Perfluorocarbures
PRG	Potentiel de Réchauffement Global
SNAP	Selected Nomenclature for Air Pollution / Nomenclature Spécifique pour la Pollution de l'Air
Tg	1 Tg (Teragramme) = 1 000 Gg = 1 000 000 Mg = 1000 kt = 1 000 000 t
TOM	Territoire d'Outre-Mer
UNFCCC	United Nations Framework Convention on Climate Change / Convention Cadre des Nations Unies sur le Changement Climatique

annexe 1 – résultats détaillés selon le format de l'UNFCCC

Cette annexe contient les tables au format requis par l'UNFCCC (CRF) et pertinentes pour les années 1990, 1998 et 1999. L'année 1990 est fournie car elle constitue l'année de référence. L'année 1999 comportant un certain nombre de valeurs provisoires à la date du présent rapport, les tables du CRF sont fournies pour les deux dernières années de la période étudiée, à savoir 1998 et 1999.

Les résultats des années intermédiaires figurent dans les tables récapitulatives de l'année 1999.

Les modifications apportées lors de la dernière révision sont explicitées dans les tables relatives à l'année 1999 prévues à cet effet.

Les résultats concernent la France au sens métropole et outre-mer.

⁽¹⁾ Activity data should be calculated using net calorific values (NCV) as specified by the IPCC Guidelines. If gross calorific values (GCV) were used, please indicate this by replacing "NCV" with "GCV" in this column.⁽²⁾ Accurate estimation of CH₄ and N₂O emissions depends on combustion conditions, technology, and emission control policy, as well as fuel characteristics. Therefore, caution should be used when comparing the implied emission factors.⁽³⁾ Carbon dioxide emissions from biomass are reported under Memo Items. The content of the cells is not included in the totals.

Note: For the coverage of fuel categories, please refer to the IPCC Guidelines (Volume 1. Reporting Instructions - Common Reporting Framework, section 1.2, p. 1.19). If some derived gases (e.g. gas work gas, coke oven gas, blast gas, oxygen steel furnace gas, etc.) are considered, Parties should provide information on the allocation of these derived gases under the above fuel categories (liquid, solid, gaseous, biomass, other fuels) in the documentation box at the end of sheet 4 of this table.

⁽¹⁾ To convert quantities expressed in natural units to energy units, use net calorific values (NCV). If gross calorific values (GCV) are used in this table, please indicate this by replacing "NCV" with "GCV" in this column.

⁽²⁾ If Anthracite is not separately available, include with Other Bituminous Coal.

TABLE 1.A(c) COMPARISON OF CO₂ EMISSIONS FROM FUEL COMBUSTION
(Sheet 1 of 1)

France
 1999
 Submission

FUEL TYPES	Reference approach		National approach ⁽¹⁾		Difference ⁽²⁾	
	Energy consumption (PJ)	CO ₂ emissions (Gg)	Energy consumption (PJ)	CO ₂ emissions (Gg)	Energy consumption (%)	CO ₂ emissions (%)
Liquid Fuels (excluding international bunkers)	#VALEUR!	#VALEUR!	3 235.41	237 231.80	#VALEUR!	#VALEUR!
Solid Fuels (excluding international bunkers)	#VALEUR!	#VALEUR!	407.94	43 890.86	#VALEUR!	#VALEUR!
Gaseous Fuels	#VALEUR!	#VALEUR!	1 250.60	71 266.11	#VALEUR!	#VALEUR!
Other ⁽³⁾			498.16	27 202.60	-100.00	-100.00
<i>Total</i> ⁽³⁾	#VALEUR!	#VALEUR!	5 392.11	379 591.37	#VALEUR!	#VALEUR!

⁽¹⁾ "National approach" is used to indicate the approach (if different from the Reference approach) followed by the Party to estimate its CO₂ emissions from fuel combustion reported in the national GHG inventory.

⁽²⁾ Difference of the Reference approach over the National approach (i.e. difference = 100% x ((RA-NA)/NA), where NA = National approach and RA = Reference approach).

⁽³⁾ Emissions from biomass are not included.

Note: In addition to estimating CO₂ emissions from fuel combustion by sector, Parties should also estimate these emissions using the IPCC Reference approach, as found in the IPCC Guidelines, Worksheet 1-1(Volume 2. Workbook). The Reference approach is to assist in verifying the sectoral data. Parties should also complete the above tables to compare the alternative estimates, and if the emission estimates lie more than 2 percent apart, should explain the source of this difference in the documentation box provided.

Documentation Box:

Detailed data for the reference approach are not available at this time. The same method that previous years has been used for the sectoral approach.

TABLE 1.A(d) SECTORAL BACKGROUND DATA FOR ENERGY
Feedstocks and Non-Energy Use of Fuels
(Sheet 1 of 1)

France
 1999
 Submission

FUEL TYPE ⁽¹⁾	ACTIVITY DATA AND RELATED INFORMATION		IMPLIED EMISSION FACTOR Carbon emission factor (t C/TJ)	ESTIMATE of carbon stored in non energy use of fuels (Gg C)	Additional information ^(a)	
	Fuel quantity (TJ)	Fraction of carbon stored			CO ₂ not emitted (Gg CO ₂)	Subtracted from energy sector (specify source category)

Other (<i>please specify</i>) <input checked="" type="checkbox"/>			0.00			

⁽¹⁾ Where fuels are used in different industries, please enter in different rows.

⁽²⁾ Enter these fuels when they are used as feedstocks.

^(a) The fuel lines continue from the table to the left.

Note: The table is consistent with the IPCC Guidelines. Parties that take into account the emissions associated with the use and disposal of these feedstocks could continue to use their methodology, and provide explanation notes in the documentation box below.

Documentation box: A fraction of energy carriers is stored in such products as plastics or asphalt. The non-stored fraction of the carbon in the energy carrier or product is oxidized, resulting in carbon dioxide emissions, either during the use of the energy carriers in the industrial production (e.g. fertilizer production), or during the use of the products (e.g. solvents, lubricants), or in both (e.g. monomers). To report associated emissions use the above table, filling an extra "Additional information" table, as shown below.		
Associated CO ₂ emissions (Gg)	Allocated under (Specify source category) ^(a)	^(a) e.g. Industrial Processes, Waste Incineration, etc.

TABLE 1.B.1 SECTORAL BACKGROUND DATA FOR ENERGY

Fugitive Emissions from Solid Fuels

(Sheet 1 of 1)

France
1999
Submission

GREENHOUSE GAS SOURCE AND SINK CATEGORIES	ACTIVITY DATA Amount of fuel produced ⁽¹⁾ (Mt)	IMPLIED EMISSION FACTOR		EMISSIONS	
		CH ₄ (kg/t)	CO ₂ (kg/t)	CH ₄ (Gg)	CO ₂ (Gg)

1. B. 1. c. Other (please specify)⁽³⁾				13.23	0.00
Post-Mining Activities	5.09	2.60	0.00	13.23	0.00

Additional information^(a)

Description	Value
Amount of CH ₄ drained (recovered) and utilized or flared (Gg)	
Number of active underground mines	
Number of mines with drainage (recovery) systems	

^(a) For underground mines.

⁽¹⁾ Use the documentation box to specify whether the fuel amount is based on the run-of-mine (ROM) production or on the saleable production.

⁽²⁾ Emissions both for Mining Activities and Post-Mining Activities are calculated with the activity data in lines Underground Mines and Surface Mines respectively.

⁽³⁾ Please click on the button to enter any other solid fuel related activities resulting in fugitive emissions, such as emissions from abandoned mines and waste piles.

Note: There are no clear references to the coverage of 1.B.1.b. and 1.B.1.c. in the IPCC Guidelines. Make sure that the emissions entered here are not reported elsewhere. If they are reported under another source category, indicate this (IE) and make a reference in Table 9 (completeness) and/or in the documentation box.

Documentation box:

From CORINAIR system the post-mining activity is not split into both underground and surface mines, and has been therefore allocated into 1B1c - other.

1.B.2.d. Other (please specify) ⁽⁶⁾				0.00	0.00	0.00			

Additional information		
Description	Value	Unit
Pipelines length (km)		
Number of oil wells		
Number of gas wells		
Gas throughput ^(a)		
Oil throughput ^(a)		
Other relevant information (specify)		

^(a) In the context of oil and gas production, throughput is a measure of the total production, such as barrels per day of oil, or cubic meters of gas per year. Specify the units of the reported value in the unit column. Take into account that these values should be consistent with the activity data reported under the production rows of the main table.

⁽¹⁾ Specify the activity data used and fill in the activity data description column, as given in the examples in brackets. Specify the unit of the activity data in the unit column. Use the document box to specify whether the fuel amount is based on the raw material production or on the saleable production. Note cases where more than one variable is used as activity data.

⁽²⁾ The unit of the implied emission factor will depend on the units of the activity data used, and is therefore not specified in this column. The unit of the implied emission factor for each activity will be kg/unit of activity data.

⁽³⁾ Use the category also to cover emissions from combined oil and gas production fields. Natural gas processing and distribution from these fields should be included under 1.B.2.b.ii and 1.B.2.b.iii, respectively.

⁽⁴⁾ If using default emission factors these categories will include emissions from production other than venting and flaring.

⁽⁵⁾ If using default emission factors, emissions from Venting and Flaring from all oil and gas production should be accounted for here. Parties using the IPCC software could report those emissions together, indicating so in the documentation box.

⁽⁶⁾ For example, fugitive CO₂ emissions from production of geothermal power could be reported here.

Documentation box:

Multilateral Operations ⁽¹⁾							

Additional information

Fuel consumption	Allocation ^(a) (percent)	
	Domestic	International
Marine	18.53	81.47
Aviation	30.61	69.39

^(a) For calculating the allocation of fuel consumption, use the sums of fuel consumption by domestic navigation and aviation (Table 1.A(a)) and by international bunkers (Table 1.C).

⁽¹⁾ Parties may choose to report or not report the activity data and emission factors for multilateral operation consistent with the principle of confidentiality stated in the UNFCCC reporting guidelines on inventories. In any case, Parties should report the emissions from multilateral operations, where available, under the Memo Items section of the Summary tables and in the Sectoral report table for energy.

Note: In accordance with the IPCC Guidelines, international aviation and marine bunker fuel emissions from fuel sold to ships or aircraft engaged in international transport should be excluded from national totals and reported separately for informational purposes only.

Documentation box: Please explain how the consumption of international marine and aviation bunkers fuels was estimated and separated from the domestic consumption.

Aviation bunker : the fuel consumption for international aviation is deduced from the balance between the total aviation fuel sale and the estimation of the domestic traffic consumption which is calculated with a detailed approach (based on the individual aircraft movements and using ICAO, MEET and CORINAIR sources of information).

Marine bunker : the UN-ECE definition for international marine traffic is considered. Thus a part from the French bunker is counted within the international marine bunker.

⁽¹⁾ Where the IPCC Guidelines provide options for activity data, e.g. cement or clinker for estimating the emissions from Cement Production, specify the activity data used (as shown in the example in brackets) in order to make the choice of emission factor more transparent and to facilitate comparisons of implied emission factors.

⁽²⁾ Enter cases in which the final emissions are reduced with the quantities of emission recovery, oxidation, destruction, transformation. Adjusted emissions are reported and the quantitative information on recovery, oxidation, destruction, and transformation should be given in the additional columns provided.

⁽³⁾ To avoid double counting make offsetting deductions from fuel consumption (e.g. natural gas) in Ammonia Production, first for feedstock use of the fuel, and then to a sequestering use of the feedstock.

⁽³⁾ Potential emissions of each chemical of halocarbons and SF₆ estimated using Tier 1a or Tier 1b of the IPCC Guidelines (Volume 3. Reference Manual, pp. 2.47-2.50). When potential emissions estimates are available in a disaggregated manner corresponding to the subsectors for actual emissions defined on sheet 1 of this table, these should be reported in an annex to sheet 2, using the format of sheet 1, sector F(a). Use Summary 3 of this common reporting format to indicate whether Tier 1a or Tier 1b was used.

⁽⁴⁾ Production refers to production of new chemicals. Recycled substances could be included here, but it should be ensured that double counting of emissions is avoided. Relevant explanations should be provided as a comment to the corresponding cell.

⁽⁵⁾ Relevant just for Tier 1b.

⁽⁶⁾ Sums of the actual emissions of each chemical of halocarbons and SF₆ from the source categories given in sheet 1 of the table multiplied by the corresponding GWP values.

⁽⁷⁾ Potential emissions of each chemical of halocarbons and SF₆ taken from row F(p) multiplied by the corresponding GWP values.

Note: As stated in the revised UNFCCC guidelines, Parties should report actual emissions of HFCs, PFCs and SF₆, where data are available, providing disaggregated data by chemical and source category in units of mass and in CO₂ equivalents. Parties reporting actual emissions should also report potential emissions for the sources where the concept of potential emissions applies, for reasons of transparency and comparability.

⁽¹⁾ Specify the activity data used as shown in the examples within brackets. Where applying Tier 1b (for C), Tier 2 (for E) and country specific methods, specify any other relevant activity data used in the documentation box below.

⁽²⁾ Emissions and implied emission factors are after recovery.

⁽³⁾ Enter cases in which the final emissions are reported after subtracting the quantities of emission recovery, oxidation, destruction, transformation.

Enter these quantities in the specified column and use the documentation box for further explanations.

Note: Where the activity data are confidential, the entries should provide aggregate figures, but there should be a note in the documentation box indicating this.

Documentation box:

HFC and PFC production data are confidential. Only fugitive emissions are available.

Soft Foam									

⁽¹⁾ Parties should use the documentation box to provide information on the amount of the chemical recovered (recovery efficiency) and other relevant information used in the emission estimation.⁽²⁾ Please click on the button to specify the chemical consumed, as given in the example. If needed, new rows could be added for reporting the disaggregated chemicals from a source by clicking on the corresponding button.

Note: Table 2(II).F provides for reporting of the activity data and emission factors used to calculate actual emissions from consumption of halocarbons and SF₆ using the "bottom-up approach" (based on the total stock of equipment and estimated emission rates from this equipment). Some Parties may prefer to estimate their actual emissions following the alternative "top-down approach" (based on annual sales of equipment and/or gas). These Parties should provide the activity data used in the current format and any other relevant information in the documentation box at the end of Table 2(II).F.2. Data these Parties should provide includes (1) the amount of fluid used to fill new products, (2) the amount of fluid used to service existing products, (3) the amount of fluid originally used to fill retiring products (the total nameplate capacity of retiring products), (4) the product lifetime, and (5) the growth rate of product sales, if this has been used to calculate the amount of fluid originally used to fill retiring products. Alternatively, Parties may provide alternative formats with equivalent information. These formats may be considered for future versions of the common reporting format after the trial period.

⁽¹⁾ See footnote 4 to Summary 1.A of this common reporting format. Parties which choose to report CO₂ emissions and removals from agricultural soils under 4.D. Agricultural Soils category of the sector Agriculture should indicate the amount [Gg] of these emissions or removals in the documentation box to Table 4.D. Additional information (activity data, implied emissions factors) should also be provided using the relevant documentation box to Table 4.D. This table is not modified for reporting the CO₂ emissions and removals for the sake of consistency with the IPCC tables (i.e. IPCC Sectoral Report for Agriculture).

Note: The IPCC Guidelines do not provide methodologies for the calculation of CH₄ emissions, CH₄ and N₂O removals from agricultural soils, or CO₂ emissions from savanna burning or agricultural residues burning. If you have reported such data, you should provide additional information (activity data and emission factors) used to make these estimates using the relevant documentation boxes of the Sectoral background data tables.

Disaggregated list of animals ^(b)	Dairy Cattle	Non-Dairy Cattle	Other (specify)	
Indicators:				
Weight	(kg)			
Feeding situation ^(c)				
Milk yield	(kg/day)			
Work	(hrs/day)			
Pregnant	(%)			
Digestibility of feed	(%)			

^(a) Compare to Tables A-1 and A-2 of the IPCC Guidelines (Volume 3, Reference Manual, pp. 4.31-4.34). These data are relevant if Parties do not have data on average feed intake.

^(b) Disaggregate to the split actually used. Add columns to the table if necessary.

^(c) Specify feeding situation as pasture, stall fed, confined, open range, etc.

⁽¹⁾ In the documentation boxes to all Sectoral background data tables for Agriculture, Parties should provide information on whether the activity data is one year or a 3-year average.

⁽²⁾ Parties are encouraged to provide detailed livestock population data by animal type and region in a separate table below the documentation box. This consistent set of animal population statistics should be used to estimate CH₄ emissions from enteric fermentation, CH₄ and N₂O from manure management, N₂O direct emissions from soil and N₂O emissions associated with manure production, as well as emissions from the use of manure as fuel, and sewage-related emissions reported in the waste sector.

⁽³⁾ Including data on dairy heifers, if available.

Documentation box:

To calculate methane emissions a specific method based on national expert data (emission factors) is used.
 Activity data is a one year average.

		(%)							
1. Cattle	20 532						4.26		
Dairy Cattle ⁽⁴⁾	6 739						5.85		
Non-Dairy Cattle	13 793						3.48		
2. Buffalo							0.00		
3. Sheep	10 169						0.28		
4. Goats	1 333						0.28		
5. Camels and Llamas							0.00		
6. Horses	363						2.10		
7. Mules and Asses	15						2.10		
8. Swine	7 107						7.62		
9. Poultry	328 577						0.09		

⁽¹⁾ See footnote 1 to Table 4.A of this common reporting format.

⁽²⁾ Climate regions are defined in terms of annual average temperature as follows: Cool=less than 15°C; Temperate=15°C to 25°C inclusive; and Warm=greater than 25°C (see Table 4.2 of the IPCC Guidelines (Volume 3, Reference Manual, p. 4.8)).

⁽³⁾ VS=Volatile Solids; Bo=maximum methane producing capacity for manure (IPCC Guidelines (Volume 3, Reference Manual, p.4.23 and p. 4.15).

⁽⁴⁾ Including data on dairy heifers, if available.

Animal category ^(a)	Indicator	Climate region	Animal waste management system				
			Anaerobic lagoon	Liquid system	Daily spread	Solid storage and dry lot	Pasture range paddock
Dairy Cattle	MCF ^(b)	Cool					
Dairy Cattle	Allocation(%)	Temperate					
Dairy Cattle	MCF ^(b)	Warm					
Non-Dairy Cattle	MCF ^(b)	Cool					
Non-Dairy Cattle	Allocation(%)	Temperate					
Non-Dairy Cattle	MCF ^(b)	Warm					
Swine	MCF ^(b)	Cool					
Swine	Allocation(%)	Temperate					
Swine	MCF ^(b)	Warm					
Swine	MCF ^(b)	Cool					
Swine	Allocation(%)	Temperate					
Swine	MCF ^(b)	Warm					

^(a) Copy the above table as many times as necessary.

^(b) MCF = Methane Conversion Factor (IPCC Guidelines, (Volume 3, Reference Manual, p. 4.9)). In the case of use of other climate region categorization, please replace the entries in the cells with the climate regions for which the MCFs are specified.

Documentation Box:	
To calculate methane emissions a specific method based on national expert data (emission factors) is used.

Additional information

Fraction ^(a)	Description	Value
Frac _{BURN}	Fraction of crop residue burned	
Frac _{FUEL}	Fraction of livestock N excretion in excrements burned for fuel	
Frac _{GASF}	Fraction of synthetic fertilizer N applied to soils that volatilizes as NH ₃ and NOx	
Frac _{GASM}	Fraction of livestock N excretion that volatilizes as NH ₃ and NOx	
Frac _{GRAZ}	Fraction of livestock N excreted and deposited onto soil during grazing	
Frac _{LEACH}	Fraction of N input to soils that is lost through leaching and runoff	
Frac _{NCRBF}	Fraction of N in non-N-fixing crop	
Frac _{NCRO}	Fraction of N in N-fixing crop	
Frac _R	Fraction or crop residue removed from the field as crop	

^(a) Use the fractions as specified in the IPCC Guidelines (Volume 3. Reference Manual, pp. 4.92 - 4.113).

⁽¹⁾ See footnote 4 to Summary 1.A. of this common reporting format. Parties which choose to report CO₂ emissions and removals from agricultural soils under 4.D. Agricultural Soils category should indicate the amount [Gg] of these emissions or removals and relevant additional information (activity data, implied emissions factors) in the documentation box.

⁽²⁾ To convert from N₂O-N to N₂O emissions, multiply by 44/28.

Documentation box:

Atmospheric deposition is not taken into account because of a risk of double counting.

A specific document describing the methodology used to estimate N₂O emissions from agriculture is available at CITEPA ("Méthodologie utilisée pour les inventaires de NH₃ et de N₂O provenant des activités agricoles : évolution et perspectives").

	Other (specify) <input checked="" type="checkbox"/>				0.00	
Boreal					0.00	
		Number of trees (1000s of trees)	Annual growth rate (kt dm/1000 trees)	Carbon uptake factor (t C/tree)	Carbon uptake increment (Gg C)	
Non-Forest Trees (specify type)	<input checked="" type="checkbox"/>				0.00	
					Total annual growth increment (Gg C)	49 865.55
					Gg CO ₂	182 840.35

	Amount of biomass removed (kt dm)	Carbon emission factor (t C/t dm)	Carbon release (Gg C)
Total biomass removed in Commercial Harvest	18 832.80	0.50	9 415.77
Traditional Fuelwood Consumed	19 584.10	0.50	9 792.05
Total Other Wood Use		0.00	
Total Biomass Consumption from Stocks ⁽¹⁾ (Gg C)		19 207.82	
Other Changes in Carbon Stocks ⁽²⁾ (Gg C)			
		Gg CO ₂	70 428.67
Net annual carbon uptake (+) or release (-) (Gg C)			30 657.73
Net CO ₂ emissions (-) or removals (+) (Gg CO ₂)			112 411.68

⁽¹⁾ Make sure that the quantity of biomass burned off-site is subtracted from this total.⁽²⁾ The net annual carbon uptake/release is determined by comparing the annual biomass growth versus annual harvest, including the decay of forest products and slash left during harvest. The IPCC Guidelines recommend default assumption that all carbon removed in wood and other biomass from forests is oxidized in the year of removal. The emissions from decay could be included under Other Changes in Carbon Stocks.

Note: Sectoral background data tables on Land-Use Change and Forestry should be filled in only by Parties using the IPCC default methodology.

Parties that use country specific methods and models should report information on them in a transparent manner, also providing suggestions for a possible sectoral background data table suitable for their calculation method.

Documentation box:
1) As regards the biomass stock item for the commercial harvest, data are compiled under the 1000 m ³ unit;
2) Consequently to 1), the corresponding average annual growth item is expressed in t dm per annum;
3) Figures mentioned in 1) and 2) are temporary data, taken from 1998.

Fraction which oxidizes during burning (average)		
Carbon fraction of aboveground biomass (average)		
Fraction left to decay (average)		
Nitrogen-carbon ratio	0.01	

Note: Sectoral background data tables on Land-Use Change and Forestry should be filled in only by Parties using the IPCC default methodology. Parties that use country specific methods and models should report information on them in a transparent manner, also providing suggestions for a possible sectoral background data table suitable for their calculation method.

Documentation box:

Because of a certain lack of data, the average area converted item was calculated taking into account the 1992-1996 period only. This value was also used to fill in the area converted annually item, as a default value. It is emphasised that the CO₂ emissions due to the grassland conversion are included within item D.5, table 5, since such a conversion is considered as generating CO₂ emissions from soils only, according to the IPCC guidelines. As the French methodology used differs from the IPCC's, a specific document describing it is available at the CITEPA ("Evaluation des puits de CO₂ suivant la nouvelle méthode préconisée par le GIEC", CITEPA, June 1999). The average quantity of biomass left to decay regarding tropical wet vegetation is based on the annual production of harvest.

TABLE 5.D SECTORAL BACKGROUND DATA FOR LAND-USE CHANGE AND FORESTRY

CO₂ Emissions and Removals from Soil

(Sheet 1 of 1)

France

1999

Submission

GREENHOUSE GAS SOURCE AND SINK CATEGORIES	ACTIVITY DATA Land area (Mha)	IMPLIED EMISSION FACTORS Average annual rate of soil carbon uptake/removal (Mg C/ha/yr)	ESTIMATES Net change in soil carbon in mineral soils (Tg C over 20 yr)	Additional information						
				Year	Climate ^(a) (e.g. tropical, dry)	land-use/ management system ^(a) (e.g. savanna)	Soil type			
					High activity soils	Low activity soils	Sandy	Volcanic	Wetland (Aquic)	Organic soil
Cultivation of Mineral Soils ⁽¹⁾			0.00							
High Activity Soils			0.00							
Low Activity Soils			0.00							
Sandy			0.00							
Volcanic			0.00							
Wetland (Aquic)			0.00							
Other (please specify)			0.00							
	Land area (ha)	Annual loss rate (Mg C/ha/yr)	Carbon emissions from organic soils (Mg C/yr)							
Cultivation of Organic Soils			0.00							
<i>Cool Temperate</i>			0.00							
Upland Crops			0.00							
Pasture/Forest			0.00							
<i>Warm Temperate</i>			0.00							
Upland Crops			0.00							
Pasture/Forest			0.00							
<i>Tropical</i>			0.00							
Upland Crops			0.00							
Pasture/Forest			0.00							
	Total annual amount of lime (Mg)	Carbon conversion factor	Carbon emissions from liming (Mg C)							
Liming of Agricultural Soils			0.00							
Limestone Ca(CO ₃)			0.00							
Dolomite CaMg(CO ₃) ₂			0.00							
	Total annual net carbon emissions from agriculturally impacted soils (Gg C)		0.00							
	Total annual net CO ₂ emissions from agriculturally impacted soils (Gg CO ₂)		0.00							

⁽¹⁾ The information to be reported under Cultivation of Mineral Soils aggregates data per soil type over all land-use/management systems. This refers to land area data and to the emission estimates and implied emissions factors accordingly.

Note: Sectoral background data tables on Land-Use Change and Forestry should be filled in only by Parties using the IPCC default methodology. Parties that use country specific methods and models should report information on them in a transparent manner, also providing suggestions for a possible sectoral background data table suitable for their calculation method.

Documentation Box:

Since the French methodology does not treat the carbon soil release or uptake in relation to the nature of the different soils, a specific document available at the CITEPA ("Evaluation des puits de CO₂ suivant la nouvelle méthode préconisée par le GIEC", CITEPA, June 1999) develops the background processing that leads to the results presented in table 5, section D.5.

(biogenic) ⁽³⁾		0.00	0.00	0.00	13 998.32		
(plastics and other non-biogenic waste) ⁽³⁾		0.00	0.00	0.00	2 286.80		
Biogenic and non-biogenic	17 175.65	0.00	1.02	0.08		17.50	1.30

MSW - Municipal Solid Waste, SWDS - Solid Waste Disposal Site, MCF - Methane Correction Factor, DOC - Degradable Organic Carbon (IPCC Guidelines (Volume 3, Reference Manual, section 6.2.4)). MSW includes household waste, yard/garden waste, commercial/market waste and organic industrial solid waste. MSW should not include inorganic industrial waste such as construction or demolition materials.

⁽¹⁾ Actual emissions (after recovery).

⁽²⁾ CH₄ recovered and flared or utilized.

⁽³⁾ Under Waste Disposal, CO₂ emissions should be reported only when the disposed wastes are combusted at the disposal site which might constitute a management practice. CO₂ emissions from non-biogenic wastes are included in the totals, while the CO₂ emissions from biogenic wastes are not included in the totals.

Documentation box:

All relevant information used in calculation should be provided in the additional information box and in the documentation box.

Parties that use country specific models should note this with a brief rationale in the documentation box and fill the relevant cells only.

Table 6A: CH₄ emissions are calculated using a first order decay method based on tier 2. So even if no more wastes are dumped into unmanaged waste disposal sites (without any mechanical compacting) there is still some waste decomposition and CH₄ emissions.

Table 6C: 15% of the waste incineration CO₂ is considered as from biogenic waste.

Additional information: For MSW 3 CH₄ generation rate constants are used; k1 for 30% of the total wastes, k2 for 30% of the total wastes and k3 for 40% of the total wastes. Some informations are not available at this time.

^(a) Specify whether total or urban population is used and the rationale for doing so.

^(b) See IPCC Guidelines (Volume 3, Reference Manual, p. 6.9).

^(c) For Parties using Tier 2 methods.

P = Potential emissions based on Tier 1 approach of the IPCC Guidelines.

A = Actual emissions based on Tier 2 approach of the IPCC Guidelines.

⁽¹⁾ The emissions of HFCs and PFCs are to be expressed as CO₂ equivalent emissions. Data on disaggregated emissions of HFCs and PFCs are to be provided in Table 2(II) of this common reporting format.

⁽²⁾ For verification purposes, countries are asked to report the results of their calculations using the Reference approach and to explain any differences with the Sectoral approach. Where possible, the calculations using the Sectoral approach should be used for estimating national totals. Do not include the results of both the Reference approach and the Sectoral approach in national totals.

⁽³⁾ Other Production includes Pulp and Paper and Food and Drink Production.

Note: The numbering of footnotes to all tables containing more than one sheet continue to the next sheet. Common footnotes are given only once at the first point of reference.

		0.00													

⁽⁴⁾ According to the IPCC Guidelines (Volume 3. Reference Manual, pp. 4.2, 4.87), CO₂ emissions from agricultural soils are to be included under Land-Use Change and Forestry (LUCF). At the same time, the Summary Report 7A (Volume 1. Reporting Instructions, Tables.27) allows for reporting CO₂ emissions or removals from agricultural soils, either in the Agriculture sector, under D. Agricultural Soils or in the Land-Use Change and Forestry sector under D. Emissions and Removals from Soil. Parties may choose either way to report emissions or removals from this source in the common reporting format, but the way they have chosen to report should be clearly indicated, by inserting explanatory comments to the corresponding cells of Summary 1.A and Summary 1.B. Double-counting of these emissions or removals should be avoided. Parties should include these emissions or removals consistently in Table8(a) (Recalculation - Recalculated data) and Table10 (Emission trends).

⁽⁵⁾ Please do not provide an estimate of both CO₂ emissions and CO₂ removals. "Net" emissions (emissions - removals) of CO₂ should be estimated and a single number placed in either the CO₂ emissions or CO₂ removals column, as appropriate. Please note that for the purposes of reporting, the signs for uptake are always (-) and for emissions (+).

⁽⁶⁾ Note that CO₂ from Waste Disposal and Incineration source categories should only be included if it stems from non-biogenic or inorganic waste streams.

CO₂ Emissions from Biomass	36 991.58														

P = Potential emissions based on Tier 1 approach of the IPCC Guidelines.

A = Actual emissions based on Tier 2 approach of the IPCC Guidelines.

⁽¹⁾ The emissions of HFCs and PFCs are to be expressed as CO₂ equivalent emissions. Data on disaggregated emissions of HFCs and PFCs are to be provided in Table 2(II) of this common reporting format.

⁽²⁾ For verification purposes, countries are asked to report the results of their calculations using the Reference approach and to explain any differences with the Sectoral approach in document box of Table 1.A(c). Where possible, the calculations using the Sectoral approach should be used for estimating national totals. Do not include the results of both the Reference approach and the Sectoral approach in national totals.

⁽³⁾ See footnote 4 to Summary 1.A.

⁽⁴⁾ Please do not provide an estimate of both CO₂ emissions and CO₂ removals. "Net" emissions (emissions - removals) of CO₂ should be estimated and a single number placed in either the CO₂ emissions or CO₂ removals column, as appropriate. Please note that for the purposes of reporting, the signs for uptake are always (-) and for emissions (+).

SUMMARY 2 SUMMARY REPORT FOR CO₂ EQUIVALENT EMISSIONS

G. Other												

⁽¹⁾ Use the following notation keys to specify the method applied: D (IPCC default), RA (Reference Approach), T1 (IPCC Tier 1), T1a, T1b, T1c (IPCC Tier 1a, Tier 1b and Tier 1c, respectively), T2 (IPCC Tier 2), T3 (IPCC Tier 3), C (CORINAIR), CS (Country Specific), M (Model). If using more than one method, enumerate the relevant methods. Explanations of any modifications to the default IPCC methods, as well as information on the proper use of methods per source category where more than one method is indicated, and explanations on the country specific methods, should be provided in the documentation box of the relevant Sectoral background data table.

⁽²⁾ Use the following notation keys to specify the emission factor used: D (IPCC default), C (CORINAIR), CS (Country Specific), PS (Plant Specific), M (Model). Where a mix of emission factors has been used, use different notations in one and the same cells with further explanation in the documentation box of the relevant Sectoral background data table.

⁽¹⁾ This table is intended to be used by Parties to summarize their own assessment of completeness (e.g. partial, full estimate, not estimated) and quality (high, medium, low) of major source/sink inventory estimates. The latter could be understood as a quality assessment of the uncertainty of the estimates. This table might change once the IPCC completes its work on managing uncertainties of GHG inventories. The title of the table was kept for consistency with the current table in the IPCC Guidelines.

Note: To fill in the table use the notation key as given in the IPCC Guidelines (Volume 1. Reporting Instructions, Tables. 37).

⁽¹⁾ Estimate the percentage change due to recalculation with respect to the previous submission (Percentage change = 100% x [(LS-PS)/PS], where LS = Latest submission and PS = Previous submission.

All cases of recalculation of the estimate of the source/sink category, should be addressed and explained in Table 8(b) of this common reporting format.

⁽²⁾ See footnote 4 to Summary 1.A of this common reporting format.

TABLE 8(b) RECALCULATION - EXPLANATORY INFORMATION
 (Sheet 1 of 1)

France
 1999
 Submission

Specify the sector and source/sink category ⁽¹⁾ where changes in estimates have occurred:		GHG	RECALCULATION DUE TO			Addition/removal/ replacement of source/sink categories	
			CHANGES IN:				
			Methods ⁽²⁾	Emission factors ⁽²⁾	Activity data ⁽²⁾		
1A1	Energy industries	CO2, CH4, N2O			Retroactive energy statistic review for years 1996 to 1998		
1A2	Manufacturing Industries and Construction	CO2, CH4, N2O			Complete review of biomass fuel consumption (new statistics for years 1990 to 1998)		
1A4	Other Sectors	CO2, CH4, N2O			Complete review of biomass fuel consumption (new statistics for years 1990 to 1998). Updating of district heating data for year 1997 and provisional updating for 1998. Because 1998 and 1999 data are not available at this time, 1997 figures are reported.		
1A3a	Civil aviation (1990-1998)	CO2	Improvements of the methodology resulting from a French working group on CO2 evaluation from air traffic, managed by the DGAC (Direction Générale de l'Aviation Civile).	General improvements for cruise calculation. Specific improvements for turboprop aircraft which was previously overestimated.	Decrease of the fuel consumption for the domestic aviation as a consequence of the methodology review.		
1A3b	Road transport (1990-1998)	CO2, CH4, N2O	Changes within the national road traffic statistics during the year 2000 from the transport Ministry for the years 1990-1999 in one hand, and in the other hand, energy balance based on fuel delivery instead of fuel sales.		Globally small decrease of the fuel consumption compared to the previous submission. At a more detailed level, increase of the heavy duty vehicles contribution and decrease of the motorcycles contribution.		
	Memo items : International aviation (1990-1998)	CO2	The international aviation fuel consumption is based on the balance between the total French aviation fuel sales and the calculated domestic aviation consumption.		Increase of the fuel consumption for the international aviation as a consequence of the decrease of the domestic aviation fuel consumption.		
1B2	Fugitive Emissions from Oil and Natural Gas	N2O	N2O emissions from this category are not included in the CRF. They were taken into account previously.				
2B	Chemical Industry	N2O	updating of emission data (direct input in 1998)				
2C1	Metal production	CH4	excluded from the CRF, taken into account previously.				
2F	Consumption of Halocarbons	HFCs			updating of activity data for the refrigeration and air conditionning sector (1994-1998)		

2F	Consumption of Halocarbons	PFCs			updating of activity data (1990-1998)	
2F	Consumption of Halocarbons	SF6			updating of activity data for the electrical equipments sector (1990-1998)	
3	Solvent use (1990-1998)	CO2	Within CRF, NMVOCs from category 3C are not converted into CO2, but they were converted previously.			Removal of 3C contribution within CRF compared to previous IPCC table 3 submission.
4C	Rice Cultivation	N2O	excluded from the CRF, taken into account previously.			
4D	Agricultural Soils	N2O	for Nitrogen leaching and run off (represents a minor source of N2O)	EF has been divided by 20 due to the improvement of knowledge.	Activity data have been approximately multiplied by 2 for all years. (new statistics)	
5A	Changes in Forest and Other Woody Biomass Stock	CO2			updating of statistic data (1998)	
5B	Forest and Grassland Conversion	N2O	Using in the previous submission the "ReportER" software, some rounded figures were used in the previous table 5 (especially for oversea territories). The conversion in CO2 equivalent consequently makes some differences.			
5D	CO2 Emissions and Removals from Soils	CO2			updating of statistic data (1998)	
6A	Solid Waste Disposal on Land	CH4	Emissions are now calculated using the FOD method. The previous submission was based on tier 1 IPCC.			
6B	Wastewater Handling	CH4, N2O			updating of the population inventory in 1999	
6C	Waste Incineration	CO2, CH4, N2O			updating of activity data (1997-1998)	

⁽¹⁾ Enter the identification code of the source/sink category (e.g. 1.B.1) in the first column and the name of the category (e.g. Fugitive Emissions from Solid Fuels) in the second column of the table (see Table 8(a)).

⁽²⁾ Explain changes in methods, emission factors and activity data that have resulted in recalculation of the estimate of the source/sink as indicated in Table 8(a). Include relevant changes in the assumptions and coefficients under the "Methods" column.

Documentation box: Use the documentation box to report the justifications of the changes as to improvements in the accuracy, completeness and consistency of the inventory.

Some differences (< 0.5%) are due to rounded figures used in the previous submission.

TABLE 9 COMPLETENESS

 Submission

Sources and sinks not reported (NE) ⁽¹⁾				
GHG	Sector ⁽²⁾	Source/sink category ⁽²⁾	Explanation	
CO ₂				
CH ₄	1A3. Transport	Civil Aviation	neglected	
	Transport	Marine national / international	neglected	
N ₂ O	4D. Agricultural Soils	Atmospheric Deposition	not included because of possible double counting	
	1A3. Transport	Civil Aviation	neglected	
HFCs				
PFCs				
SF ₆	2. Industrial process	Consumption of SF ₆ from various minor applications (window insulation, tennis balls etc.) - neglected		
Sources and sinks reported elsewhere (IE) ⁽³⁾				
GHG	Source/sink category	Allocation as per IPCC Guidelines	Allocation used by the Party	Explanation
CO ₂	1A2a-e		1A2f	Not available in the national inventory database at this time
CH ₄	1A2a-e		1A2f	Not available in the national inventory database at this time
N ₂ O	1A2a-e		1A2f	Not available in the national inventory database at this time
HFCs				
PFCs				
SF ₆				

⁽¹⁾ Please, clearly indicate sources and sinks which are considered in the IPCC Guidelines but are not considered in the submitted inventory. Explain the reason for excluding these sources and sinks, in order to avoid arbitrary interpretations. An entry should be made for each source/sink category for which the indicator "NE" is entered in the sectoral tables.

⁽²⁾ Indicate omitted source/sink following the IPCC source/sink category structure (e.g. sector: Waste, source category: Wastewater Handling).

⁽³⁾ Please clearly indicate sources and sinks in the submitted inventory that are allocated to a sector other than that indicated by the IPCC Guidelines. Show the sector indicated in the IPCC Guidelines and the sector to which the source or sink is allocated in the submitted inventory. Explain the reason for reporting these sources and sinks in a different sector. An entry should be made for each source/sink for which the indicator "IE" is used in the sectoral tables.

⁽¹⁾ Activity data should be calculated using net calorific values (NCV) as specified by the IPCC Guidelines. If gross calorific values (GCV) were used, please indicate this by replacing "NCV" with "GCV" in this column.⁽²⁾ Accurate estimation of CH₄ and N₂O emissions depends on combustion conditions, technology, and emission control policy, as well as fuel characteristics. Therefore, caution should be used when comparing the implied emission factors.⁽³⁾ Carbon dioxide emissions from biomass are reported under Memo Items. The content of the cells is not included in the totals.

Note: For the coverage of fuel categories, please refer to the IPCC Guidelines (Volume 1. Reporting Instructions - Common Reporting Framework, section 1.2, p. 1.19). If some derived gases (e.g. gas work gas, coke oven gas, blast gas, oxygen steel furnace gas, etc.) are considered, Parties should provide information on the allocation of these derived gases under the above fuel categories (liquid, solid, gaseous, biomass, other fuels) in the documentation box at the end of sheet 4 of this table.

⁽¹⁾ To convert quantities expressed in natural units to energy units, use net calorific values (NCV). If gross calorific values (GCV) are used in this table, please indicate this by replacing "NCV" with "GCV" in this column.

⁽²⁾ If Anthracite is not separately available, include with Other Bituminous Coal.

TABLE 1.A(c) COMPARISON OF CO₂ EMISSIONS FROM FUEL COMBUSTION
(Sheet 1 of 1)

France
 1998
 Submission

FUEL TYPES	Reference approach		National approach ⁽¹⁾		Difference ⁽²⁾	
	Energy consumption (PJ)	CO ₂ emissions (Gg)	Energy consumption (PJ)	CO ₂ emissions (Gg)	Energy consumption (%)	CO ₂ emissions (%)
Liquid Fuels (excluding international bunkers)	3 873.70	232 781.32	3 249.49	237 815.45	19.21	-2.12
Solid Fuels (excluding international bunkers)	770.21	70 725.86	474.62	50 424.47	62.28	40.26
Gaseous Fuels	1 419.69	73 877.63	1 224.78	69 793.73	15.91	5.85
Other ⁽³⁾			486.45	26 515.14	-100.00	-100.00
Total⁽³⁾	6 063.59	377 384.81	5 435.35	384 548.79	11.56	-1.86

⁽¹⁾ "National approach" is used to indicate the approach (if different from the Reference approach) followed by the Party to estimate its CO₂ emissions from fuel combustion reported in the national GHG inventory.

⁽²⁾ Difference of the Reference approach over the National approach (i.e. difference = 100% x ((RA-NA)/NA), where NA = National approach and RA = Reference approach).

⁽³⁾ Emissions from biomass are not included.

Note: In addition to estimating CO₂ emissions from fuel combustion by sector, Parties should also estimate these emissions using the IPCC Reference approach, as found in the IPCC Guidelines, Worksheet 1-1(Volume 2. Workbook). The Reference approach is to assist in verifying the sectoral data. Parties should also complete the above tables to compare the alternative estimates, and if the emission estimates lie more than 2 percent apart, should explain the source of this difference in the documentation box provided.

Documentation Box:

Anthracite is included with "other bituminous coal» and gaseous biomass is included in liquid biomass.

The reference approach is applied to the metropolitan area only. The apparent difference in fuel categories is due to different allocation of derived fuels between the reference approach and the sectoral approach. Difference are also due to maritime and air traffics which are differently counted in the sectoral and the reference approaches.

418.88	
487.12	
-7 406.67	
0.00	

^(a) The fuel lines continue from the table to the left.

Note: The table is consistent with the IPCC Guidelines. Parties that take into account the emissions associated with the use and disposal of these feedstocks could continue to use their methodology, and provide explanation notes in the documentation box below.

Documentation box: A fraction of energy carriers is stored in such products as plastics or asphalt. The non-stored fraction of the carbon in the energy carrier or product is oxidized, resulting in carbon dioxide emissions, either during the use of the energy carriers in the industrial production (e.g. fertilizer production), or during the use of the products (e.g. solvents, lubricants), or in both (e.g. monomers). To report associated emissions use the above table, filling an extra "Additional information" table, as shown below.

Associated CO ₂ emissions (Gg)	Allocated under (Specify source category) ^(a)	^(a) e.g. Industrial Processes, Waste Incineration, etc.
2 298.00	6C non-biogenic	
1 647.00	3A, B, D	
4 144.53	1B2	

Butane is included with LPG.

Post-Mining Activities	5.60	2.64	0.00	14.79	0.00

Additional information^(a)

Description	Value
Amount of CH ₄ drained (recovered) and utilized or flared (Gg)	
Number of active underground mines	
Number of mines with drainage (recovery) systems	

^(a) For underground mines.

⁽¹⁾ Use the documentation box to specify whether the fuel amount is based on the run-of-mine (ROM) production or on the saleable production.

⁽²⁾ Emissions both for Mining Activities and Post-Mining Activities are calculated with the activity data in lines Underground Mines and Surface Mines respectively.

⁽³⁾ Please click on the button to enter any other solid fuel related activities resulting in fugitive emissions, such as emissions from abandoned mines and waste piles.

Note: There are no clear references to the coverage of 1.B.1.b. and 1.B.1.c. in the IPCC Guidelines. Make sure that the emissions entered here are not reported elsewhere. If they are reported under another source category, indicate this (IE) and make a reference in Table 9 (completeness) and/or in the documentation box.

Documentation box:

From CORINAIR system the post-mining activity is not split into both underground and surface mines, and has been therefore allocated into 1B1c - other.

Additional information

Description	Value	Unit
Pipelines length (km)		
Number of oil wells		
Number of gas wells		
Gas throughput ^(a)		
Oil throughput ^(a)		
Other relevant information (specify)	■	

^(a) In the context of oil and gas production, throughput is a measure of the total production, such as barrels per day of oil, or cubic meters of gas per year. Specify the units of the reported value in the unit column. Take into account that these values should be consistent with the activity data reported under the production rows of the main table.

⁽¹⁾ Specify the activity data used and fill in the activity data description column, as given in the examples in brackets. Specify the unit of the activity data in the unit column. Use the document box to specify whether the fuel amount is based on the raw material production or on the saleable production. Note cases where more than one variable is used as activity data.

⁽²⁾ The unit of the implied emission factor will depend on the units of the activity data used, and is therefore not specified in this column. The unit of the implied emission factor for each activity will be kg/unit of activity data.

⁽³⁾ Use the category also to cover emissions from combined oil and gas production fields. Natural gas processing and distribution from these fields should be included under 1.B.2.b.ii and 1.B.2.b.iii, respectively.

⁽⁴⁾ If using default emission factors these categories will include emissions from production other than venting and flaring.

⁽⁵⁾ If using default emission factors, emissions from Venting and Flaring from all oil and gas production should be accounted for here. Parties using the IPCC software could report those emissions together, indicating so in the documentation box.

⁽⁶⁾ For example, fugitive CO₂ emissions from production of geothermal power could be reported here.

Documentation box:

Marine	17.60	82.40
Aviation	33.12	66.88

^(a) For calculating the allocation of fuel consumption, use the sums of fuel consumption by domestic navigation and aviation (Table 1.A(a)) and by international bunkers (Table 1.C).

⁽¹⁾ Parties may choose to report or not report the activity data and emission factors for multilateral operation consistent with the principle of confidentiality stated in the UNFCCC reporting guidelines on inventories. In any case, Parties should report the emissions from multilateral operations, where available, under the Memo Items section of the Summary tables and in the Sectoral report table for energy.

Note: In accordance with the IPCC Guidelines, international aviation and marine bunker fuel emissions from fuel sold to ships or aircraft engaged in international transport should be excluded from national totals and reported separately for informational purposes only.

Documentation box: Please explain how the consumption of international marine and aviation bunkers fuels was estimated and separated from the domestic consumption.

Aviation bunker : the fuel consumption for international aviation is deduced from the balance between the total aviation fuel sale and the estimation of the domestic traffic consumption which is calculated with a detailed approach (based on the individual aircraft movements and using ICAO, MEET and CORINAIR sources of information).

Marine bunker : the UN-ECE definition for international marine traffic is considered. Thus a part from the French bunker is counted within the international marine bunker.

⁽¹⁾ Where the IPCC Guidelines provide options for activity data, e.g. cement or clinker for estimating the emissions from Cement Production, specify the activity data used (as shown in the example in brackets) in order to make the choice of emission factor more transparent and to facilitate comparisons of implied emission factors.

⁽²⁾ Enter cases in which the final emissions are reduced with the quantities of emission recovery, oxidation, destruction, transformation. Adjusted emissions are reported and the quantitative information on recovery, oxidation, destruction, and transformation should be given in the additional columns provided.

⁽³⁾ To avoid double counting make offsetting deductions from fuel consumption (e.g. natural gas) in Ammonia Production, first for feedstock use of the fuel, and then to a sequestering use of the feedstock.

⁽³⁾ Potential emissions of each chemical of halocarbons and SF₆ estimated using Tier 1a or Tier 1b of the IPCC Guidelines (Volume 3. Reference Manual, pp. 2.47-2.50). When potential emissions estimates are available in a disaggregated manner corresponding to the subsectors for actual emissions defined on sheet 1 of this table, these should be reported in an annex to sheet 2, using the format of sheet 1, sector F(a). Use Summary 3 of this common reporting format to indicate whether Tier 1a or Tier 1b was used.

⁽⁴⁾ Production refers to production of new chemicals. Recycled substances could be included here, but it should be ensured that double counting of emissions is avoided. Relevant explanations should be provided as a comment to the corresponding cell.

⁽⁵⁾ Relevant just for Tier 1b.

⁽⁶⁾ Sums of the actual emissions of each chemical of halocarbons and SF₆ from the source categories given in sheet 1 of the table multiplied by the corresponding GWP values.

⁽⁷⁾ Potential emissions of each chemical of halocarbons and SF₆ taken from row F(p) multiplied by the corresponding GWP values.

Note: As stated in the revised UNFCCC guidelines, Parties should report actual emissions of HFCs, PFCs and SF₆, where data are available, providing disaggregated data by chemical and source category in units of mass and in CO₂ equivalents. Parties reporting actual emissions should also report potential emissions for the sources where the concept of potential emissions applies, for reasons of transparency and comparability.

⁽¹⁾ Specify the activity data used as shown in the examples within brackets. Where applying Tier 1b (for C), Tier 2 (for E) and country specific methods, specify any other relevant activity data used in the documentation box below.

⁽²⁾ Emissions and implied emission factors are after recovery.

⁽³⁾ Enter cases in which the final emissions are reported after subtracting the quantities of emission recovery, oxidation, destruction, transformation.

Enter these quantities in the specified column and use the documentation box for further explanations.

Note: Where the activity data are confidential, the entries should provide aggregate figures, but there should be a note in the documentation box indicating this.

Documentation box:

HFC and PFC production data are confidential. Only fugitive emissions are available.

⁽¹⁾ Parties should use the documentation box to provide information on the amount of the chemical recovered (recovery efficiency) and other relevant information used in the emission estimation.⁽²⁾ Please click on the button to specify the chemical consumed, as given in the example. If needed, new rows could be added for reporting the disaggregated chemicals from a source by clicking on the corresponding button.

Note: Table 2(II).F provides for reporting of the activity data and emission factors used to calculate actual emissions from consumption of halocarbons and SF₆ using the "bottom-up approach" (based on the total stock of equipment and estimated emission rates from this equipment). Some Parties may prefer to estimate their actual emissions following the alternative "top-down approach" (based on annual sales of equipment and/or gas). These Parties should provide the activity data used in the current format and any other relevant information in the documentation box at the end of Table 2(II).F.2. Data these Parties should provide includes (1) the amount of fluid used to fill new products, (2) the amount of fluid used to service existing products, (3) the amount of fluid originally used to fill retiring products (the total nameplate capacity of retiring products), (4) the product lifetime, and (5) the growth rate of product sales, if this has been used to calculate the amount of fluid originally used to fill retiring products. Alternatively, Parties may provide alternative formats with equivalent information. These formats may be considered for future versions of the common reporting format

⁽¹⁾ See footnote 4 to Summary 1.A of this common reporting format. Parties which choose to report CO₂ emissions and removals from agricultural soils under 4.D. Agricultural Soils category of the sector Agriculture should indicate the amount [Gg] of these emissions or removals in the documentation box to Table 4.D. Additional information (activity data, implied emissions factors) should also be provided using the relevant documentation box to Table 4.D. This table is not modified for reporting the CO₂ emissions and removals for the sake of consistency with the IPCC tables (i.e. IPCC Sectoral Report for Agriculture).

Note: The IPCC Guidelines do not provide methodologies for the calculation of CH₄ emissions, CH₄ and N₂O removals from agricultural soils, or CO₂ emissions from savanna burning or agricultural residues burning. If you have reported such data, you should provide additional information (activity data and emission factors) used to make these estimates using the relevant documentation boxes of the Sectoral background data tables.

Additional information (for Tier 2)^(a)

Disaggregated list of animals ^(b)	Dairy Cattle	Non-Dairy Cattle	Other (specify)	
Indicators:				
Weight	(kg)			
Feeding situation ^(c)				
Milk yield	(kg/day)			
Work	(hrs/day)			
Pregnant	(%)			
Digestibility of feed	(%)			

^(a) Compare to Tables A-1 and A-2 of the IPCC Guidelines (Volume 3, Reference Manual, pp. 4.31-4.34). These data are relevant if Parties do not have data on average feed intake.

^(b) Disaggregate to the split actually used. Add columns to the table if necessary.

^(c) Specify feeding situation as pasture, stall fed, confined, open range, etc.

⁽¹⁾ In the documentation boxes to all Sectoral background data tables for Agriculture, Parties should provide information on whether the activity data is one year or a 3-year average.

⁽²⁾ Parties are encouraged to provide detailed livestock population data by animal type and region in a separate table below the documentation box. This consistent set of animal population statistics should be used to estimate CH₄ emissions from enteric fermentation, CH₄ and N₂O from manure management, N₂O direct emissions from soil and N₂O emissions associated with manure production, as well as emissions from the use of manure as fuel, and sewage-related emissions reported in the waste sector.

⁽³⁾ Including data on dairy heifers, if available.

Documentation box:

To calculate methane emissions a specific method based on national expert data (emission factors) is used.
 Activity data is a one year average.

Water Depth > 100 cm				0.00	
4. Other (please specify)					0.00
				0.00	
Upland Rice ⁽⁴⁾					
Total ⁽⁴⁾	0.23				

⁽¹⁾ The implied emission factor takes account of all relevant corrections for continuously flooded fields without organic amendment plus the correction for the organic amendments, if used, as well as of the effect of different soil characteristics, if taken into account, on methane emissions.

⁽²⁾ Harvested area is the cultivated area multiplied by the number of cropping seasons per year.

⁽³⁾ Specify dry weight or wet weight for organic amendments.

⁽⁴⁾ These rows are included to allow comparison with the international statistics. Upland rice emissions are assumed to be zero and are ignored in the emission calculations.

Documentation box:

When disaggregating by more than one region within a country, provide additional information in the documentation box.

Where available, provide activity data and scaling factors by soil type and rice cultivar.

Additional information

Fraction ^(a)	Description	Value
Frac _{BURN}	Fraction of crop residue burned	
Frac _{FUEL}	Fraction of livestock N excretion in excrements burned for fuel	
Frac _{GASF}	Fraction of synthetic fertilizer N applied to soils that volatilizes as NH ₃ and NOx	
Frac _{GASM}	Fraction of livestock N excretion that volatilizes as NH ₃ and NOx	
Frac _{GRAZ}	Fraction of livestock N excreted and deposited onto soil during grazing	
Frac _{LEACH}	Fraction of N input to soils that is lost through leaching and runoff	
Frac _{NCRBF}	Fraction of N in non-N-fixing crop	
Frac _{NCRO}	Fraction of N in N-fixing crop	
Frac _R	Fraction or crop residue removed from the field as crop	

^(a) Use the fractions as specified in the IPCC Guidelines (Volume 3. Reference Manual, pp. 4.92 - 4.113).

⁽¹⁾ See footnote 4 to Summary 1.A. of this common reporting format. Parties which choose to report CO₂ emissions and removals from agricultural soils under 4.D. Agricultural Soils category should indicate the amount [Gg] of these emissions or removals and relevant additional information (activity data, implied emissions factors) in the documentation box.

⁽²⁾ To convert from N₂O-N to N₂O emissions, multiply by 44/28.

Documentation box:

Atmospheric deposition is not taken into account because of a risk of double counting.

A specific document describing the methodology used to estimate N₂O emissions from agriculture is available at CITEPA ("Méthodologie utilisée pour les inventaires de NH₃ et N₂O provenant des activités agricoles: évolution et perspectives").

	Other (specify) <input checked="" type="checkbox"/>				0.00	
Boreal						0.00
			Number of trees (1000s of trees)	Annual growth rate (kt dm/1000 trees)	Carbon uptake factor (t C/tree)	Carbon uptake increment (Gg C)
Non-Forest Trees (specify type) <input checked="" type="checkbox"/>						0.00
						Total annual growth increment (Gg C) 49 562.55
						Gg CO ₂ 181 729.35

	Amount of biomass removed (kt dm)	Carbon emission factor (t C/t dm)	Carbon release (Gg C)
Total biomass removed in Commercial Harvest	18 748.00	0.50	9 373.50
Traditional Fuelwood Consumed	19 470.00	0.50	9 735.00
Total Other Wood Use		0.00	
Total Biomass Consumption from Stocks ⁽¹⁾ (Gg C)			19 108.50
Other Changes in Carbon Stocks ⁽²⁾ (Gg C)			
		Gg CO ₂	70 064.50
Net annual carbon uptake (+) or release (-) (Gg C)			30 454.05
Net CO ₂ emissions (-) or removals (+) (Gg CO ₂)			111 664.85

⁽¹⁾ Make sure that the quantity of biomass burned off-site is subtracted from this total.⁽²⁾ The net annual carbon uptake/release is determined by comparing the annual biomass growth versus annual harvest, including the decay of forest products and slash left during harvest. The IPCC Guidelines recommend default assumption that all carbon removed in wood and other biomass from forests is oxidized in the year of removal. The emissions from decay could be included under Other Changes in Carbon Stocks.

Note: Sectoral background data tables on Land-Use Change and Forestry should be filled in only by Parties using the IPCC default methodology.

Parties that use country specific methods and models should report information on them in a transparent manner, also providing suggestions for a possible sectoral background data table suitable for their calculation method.

Documentation box:
1) As regards the biomass stock item for the commercial harvest, data are compiled under the 1000 m ³ unit;
2) Consequently to 1), the corresponding average annual growth item is expressed in t dm per annum;

Total annual CO ₂ emissions (Gg CO ₂)	24 678.89	

Additional information		
Fractions	On site	Off site
Fraction of biomass burned (average)	0.20	0.80
Fraction which oxidizes during burning (average)		
Carbon fraction of aboveground biomass (average)		
Fraction left to decay (average)		
Nitrogen-carbon ratio	0.01	

Note: Sectoral background data tables on Land-Use Change and Forestry should be filled in only by Parties using the IPCC default methodology. Parties that use country specific methods and models should report information on them in a transparent manner, also providing suggestions for a possible sectoral background data table suitable for their calculation method.

Documentation box:

Because of a certain lack of data, the average area converted item was calculated taking into account the 1992-1996 period only. This value was also used to fill in the area converted annually item, as a default value.

It is emphasised that the CO₂ emissions due to the grassland conversion are included within item D.5, table 5, since such a conversion is considered as generating CO₂ emissions from soils only, according to the IPCC guidelines.

As the French methodology used differs from the IPCC's, a specific document describing it is available at the CITEPA ("Evaluation des puits de CO₂ suivant la nouvelle méthode préconisée par le GIEC", CITEPA, June 1999).

The average quantity of biomass left to decay regarding tropical wet vegetation is based on the annual production of harvest.

	Total annual net CO ₂ emissions from agriculturally impacted soils (Gg CO ₂)			0.00					

⁽¹⁾ The information to be reported under Cultivation of Mineral Soils aggregates data per soil type over all land-use/management systems. This refers to land area data and to the emission estimates and implied emissions factors accordingly.

Note: Sectoral background data tables on Land-Use Change and Forestry should be filled in only by Parties using the IPCC default methodology. Parties that use country specific methods and models should report information on them in a transparent manner, also providing suggestions for a possible sectoral background data table suitable for their calculation method.

Documentation Box:

Since the French methodology does not treat the carbon soil release or uptake in relation to the nature of the different soils, a specific document available at the CITEPA ("Evaluation des puits de CO₂ suivant la nouvelle méthode préconisée par le GIEC", CITEPA, June 1999) develops the background processing that leads to the results presented in table 5, section D.5.

Year	Climate ^(a)	land-use/ management system ^(a)	Soil type			
			High activity soils	Low activity soils	Sandy	Volcanic
percent distribution (%)						
20 years prior	(e.g. tropical, dry)	(e.g. savanna)				
inventory year	(e.g. irrigated cropping)					

^(a) These should represent the major types of land management systems per climate regions presented in the country as well as ecosystem types which were either converted to agriculture (e.g., forest, savanna, grassland) or have been derived from previous agricultural land-use (e.g., abandoned lands, reforested lands). Systems should also reflect differences in soil carbon stocks that can be related to differences in management (IPCC Guidelines (Volume 2. Workbook, Table 5-9, p. 5.26, and Appendix (pp. 5-31 - 5.38)).

MSW - Municipal Solid Waste, SWDS - Solid Waste Disposal Site, MCF - Methane Correction Factor, DOC - Degradable Organic Carbon

(IPCC Guidelines (Volume 3. Reference Manual, section 6.2.4)). MSW includes household waste, yard/garden waste, commercial/market waste and organic industrial solid waste. MSW should not include inorganic industrial waste such as construction or demolition materials.

⁽¹⁾ Actual emissions (after recovery).

⁽²⁾ CH₄ recovered and flared or utilized.

⁽³⁾ Under Waste Disposal, CO₂ emissions should be reported only when the disposed wastes are combusted at the disposal site which might constitute a management practice.

CO₂ emissions from non-biogenic wastes are included in the totals, while the CO₂ emissions from biogenic wastes are not included in the totals.

^(a) Specify whether total or urban population is used and the rationale for doing so.

^(b) See IPCC Guidelines (Volume 3. Reference Manual, p. 6.9).

^(c) For Parties using Tier 2 methods.

Documentation box:

All relevant information used in calculation should be provided in the additional information box and in the documentation box.

Parties that use country specific models should note this with a brief rationale in the documentation box and fill the relevant cells only.

Table 6A: CH4 emissions are calculated using a first order decay method based on tier 2.

Table 6C: 15% of the waste incineration CO₂ is considered as from biogenic waste.

Additional information: For MSW 3 CH4 generation rate constants are used; k1 for 30% of the total wastes, k2 for 30% of the total wastes and k3 for 40% of the total wastes.

P = Potential emissions based on Tier 1 approach of the IPCC Guidelines.

A = Actual emissions based on Tier 2 approach of the IPCC Guidelines.

⁽¹⁾ The emissions of HFCs and PFCs are to be expressed as CO₂ equivalent emissions. Data on disaggregated emissions of HFCs and PFCs are to be provided in Table 2(II) of this common reporting format.

⁽²⁾ For verification purposes, countries are asked to report the results of their calculations using the Reference approach and to explain any differences with the Sectoral approach. Where possible, the calculations using the Sectoral approach should be used for estimating national totals. Do not include the results of both the Reference approach and the Sectoral approach in national totals.

⁽³⁾ Other Production includes Pulp and Paper and Food and Drink Production.

Note: The numbering of footnotes to all tables containing more than one sheet continue to the next sheet. Common footnotes are given only once at the first point of reference.

		0.00													

⁽⁴⁾ According to the IPCC Guidelines (Volume 3. Reference Manual, pp. 4.2, 4.87), CO₂ emissions from agricultural soils are to be included under Land-Use Change and Forestry (LUCF). At the same time, the Summary Report 7A (Volume 1. Reporting Instructions, Tables.27) allows for reporting CO₂ emissions or removals from agricultural soils, either in the Agriculture sector, under D. Agricultural Soils or in the Land-Use Change and Forestry sector under D. Emissions and Removals from Soil. Parties may choose either way to report emissions or removals from this source in the common reporting format, but the way they have chosen to report should be clearly indicated, by inserting explanatory comments to the corresponding cells of Summary 1.A and Summary 1.B. Double-counting of these emissions or removals should be avoided. Parties should include these emissions or removals consistently in Table8(a) (Recalculation - Recalculated data) and Table10 (Emission trends).

⁽⁵⁾ Please do not provide an estimate of both CO₂ emissions and CO₂ removals. "Net" emissions (emissions - removals) of CO₂ should be estimated and a single number placed in either the CO₂ emissions or CO₂ removals column, as appropriate. Please note that for the purposes of reporting, the signs for uptake are always (-) and for emissions (+).

⁽⁶⁾ Note that CO₂ from Waste Disposal and Incineration source categories should only be included if it stems from non-biogenic or inorganic waste streams.

G. Other												

⁽¹⁾ Use the following notation keys to specify the method applied: D (IPCC default), RA (Reference Approach), T1 (IPCC Tier 1), T1a, T1b, T1c (IPCC Tier 1a, Tier 1b and Tier 1c, respectively), T2 (IPCC Tier 2), T3 (IPCC Tier 3), C (CORINAIR), CS (Country Specific), M (Model). If using more than one method, enumerate the relevant methods. Explanations of any modifications to the default IPCC methods, as well as information on the proper use of methods per source category where more than one method is indicated, and explanations on the country specific methods, should be provided in the documentation box of the relevant Sectoral background data table.

⁽²⁾ Use the following notation keys to specify the emission factor used: D (IPCC default), C (CORINAIR), CS (Country Specific), PS (Plant Specific), M (Model). Where a mix of emission factors has been used, use different notations in one and the same cells with further explanation in the documentation box of the relevant Sectoral background data table.

⁽¹⁾ This table is intended to be used by Parties to summarize their own assessment of completeness (e.g. partial, full estimate, not estimated) and quality (high, medium, low) of major source/sink inventory estimates. The latter could be understood as a quality assessment of the uncertainty of the estimates. This table might change once the IPCC completes its work on managing uncertainties of GHG inventories. The title of the table was kept for consistency with the current table in the IPCC Guidelines.

Note: To fill in the table use the notation key as given in the IPCC Guidelines (Volume 1. Reporting Instructions, Tables. 37).

France
 1998
 Submission

Sources and sinks not reported (NE) ⁽¹⁾				
GHG	Sector ⁽²⁾	Source/sink category ⁽²⁾	Explanation	
CO ₂				
CH ₄	1A3. Transport	Civil Aviation	neglected	
	1A3 Transport	Marine national / international	neglected	
N ₂ O	4D. Agricultural Soils	Atmospheric Deposition	not included because of possible double counting	
	1A3. Transport	Civil Aviation	neglected	
HFCs				
PFCs				
SF ₆	2. Industrial process	Consumption of SF ₆ from various minor applications (window insulation, tennis balls etc.) - neglected		
Sources and sinks reported elsewhere (IE) ⁽³⁾				
GHG	Source/sink category	Allocation as per IPCC Guidelines	Allocation used by the Party	Explanation
CO ₂	1A2a-e		1A2f	Not available in the national inventory database at this time
CH ₄	1A2a-e		1A2f	Not available in the national inventory database at this time
N ₂ O	1A2a-e		1A2f	Not available in the national inventory database at this time
HFCs				
PFCs				
SF ₆				

⁽¹⁾ Please, clearly indicate sources and sinks which are considered in the IPCC Guidelines but are not considered in the submitted inventory. Explain the reason for excluding these sources and sinks, in order to avoid arbitrary interpretations. An entry should be made for each source/sink category for which the indicator "NE" is entered in the sectoral tables.

⁽²⁾ Indicate omitted source/sink following the IPCC source/sink category structure (e.g. sector: Waste, source category: Wastewater Handling).

⁽³⁾ Please clearly indicate sources and sinks in the submitted inventory that are allocated to a sector other than that indicated by the IPCC Guidelines. Show the sector indicated in the IPCC Guidelines and the sector to which the source or sink is allocated in the submitted inventory. Explain the reason for reporting these sources and sinks in a different sector. An entry should be made for each source/sink for which the indicator "IE" is used in the sectoral tables.

⁽¹⁾ Activity data should be calculated using net calorific values (NCV) as specified by the IPCC Guidelines. If gross calorific values (GCV) were used, please indicate this by replacing "NCV" with "GCV" in this column.⁽²⁾ Accurate estimation of CH₄ and N₂O emissions depends on combustion conditions, technology, and emission control policy, as well as fuel characteristics. Therefore, caution should be used when comparing the implied emission factors.⁽³⁾ Carbon dioxide emissions from biomass are reported under Memo Items. The content of the cells is not included in the totals.

Note: For the coverage of fuel categories, please refer to the IPCC Guidelines (Volume 1. Reporting Instructions - Common Reporting Framework, section 1.2, p. 1.19). If some derived gases (e.g. gas work gas, coke oven gas, blast gas, oxygen steel furnace gas, etc.) are considered, Parties should provide information on the allocation of these derived gases under the above fuel categories (liquid, solid, gaseous, biomass, other fuels) in the documentation box at the end of sheet 4 of this table.

Other ⁽³⁾			516.51	31 432.96	-100.00	-100.00
Total⁽³⁾	5 760.64	366 324.65	4 933.27	355 945.32	16.77	2.92

⁽¹⁾ "National approach" is used to indicate the approach (if different from the Reference approach) followed by the Party to estimate its CO₂ emissions from fuel combustion reported in the national GHG inventory.

⁽²⁾ Difference of the Reference approach over the National approach (i.e. difference = 100% x ((RA-NA)/NA), where NA = National approach and RA = Reference approach).

⁽³⁾ Emissions from biomass are not included.

Note: In addition to estimating CO₂ emissions from fuel combustion by sector, Parties should also estimate these emissions using the IPCC Reference approach, as found in the IPCC Guidelines, Worksheet 1-1(Volume 2. Workbook). The Reference approach is to assist in verifying the sectoral data. Parties should also complete the above tables to compare the alternative estimates, and if the emission estimates lie more than 2 percent apart, should explain the source of this difference in the documentation box provided.

Documentation Box:

Anthracite is included with "other bituminous coal» and gaseous biomass is included in liquid biomass.

The reference approach is applied to the metropolitan area only. The apparent difference in fuel categories is due to different allocation of derived fuels between the reference approach and the sectoral approach. Difference are also due to maritime and air traffics which are differently counted in the sectoral and the reference approaches.

⁽¹⁾ Where fuels are used in different industries, please enter in different rows.

⁽²⁾ Enter these fuels when they are used as feedstocks.

^(a) The fuel lines continue from the table to the left.

Note: The table is consistent with the IPCC Guidelines. Parties that take into account the emissions associated with the use and disposal of these feedstocks could continue to use their methodology, and provide explanation notes in the documentation box below.

Documentation box: A fraction of energy carriers is stored in such products as plastics or asphalt. The non-stored fraction of the carbon in the energy carrier or product is oxidized, resulting in carbon dioxide emissions, either during the use of the energy carriers in the industrial production (e.g. fertilizer production), or during the use of the products (e.g. solvents, lubricants), or in both (e.g. monomers). To report associated emissions use the above table, filling an extra "Additional information" table, as shown below.		
Associated CO₂ emissions (Gg)	Allocated under (Specify source category)^(a)	^(a) e.g. Industrial Processes, Waste Incineration, etc.
2 132.59	6C non-biogenic

Additional information^(a)

Description	Value
Amount of CH ₄ drained (recovered) and utilized or flared (Gg)	
Number of active underground mines	
Number of mines with drainage (recovery) systems	

^(a) For underground mines.

⁽¹⁾ Use the documentation box to specify whether the fuel amount is based on the run-of-mine (ROM) production or on the saleable production.

⁽²⁾ Emissions both for Mining Activities and Post-Mining Activities are calculated with the activity data in lines Underground Mines and Surface Mines respectively.

⁽³⁾ Please click on the button to enter any other solid fuel related activities resulting in fugitive emissions, such as emissions from abandoned mines and waste piles.

Note: There are no clear references to the coverage of 1.B.1.b. and 1.B.1.c. in the IPCC Guidelines. Make sure that the emissions entered here are not reported elsewhere. If they are reported under another source category, indicate this (IE) and make a reference in Table 9 (completeness) and/or in the documentation box.

Documentation box:

From CORINAIR system the post-mining activity is not split into both underground and surface mines, and has been therefore allocated into 1B1c - other.

1.B.2.d. Other (please specify) ⁽⁶⁾				0.00	0.00	0.00			

Additional information		
Description	Value	Unit
Pipelines length (km)		
Number of oil wells		
Number of gas wells		
Gas throughput ^(a)		
Oil throughput ^(a)		
Other relevant information (specify)		

^(a) In the context of oil and gas production, throughput is a measure of the total production, such as barrels per day of oil, or cubic meters of gas per year. Specify the units of the reported value in the unit column. Take into account that these values should be consistent with the activity data reported under the production rows of the main table.

⁽¹⁾ Specify the activity data used and fill in the activity data description column, as given in the examples in brackets. Specify the unit of the activity data in the unit column. Use the document box to specify whether the fuel amount is based on the raw material production or on the saleable production. Note cases where more than one variable is used as activity data.

⁽²⁾ The unit of the implied emission factor will depend on the units of the activity data used, and is therefore not specified in this column. The unit of the implied emission factor for each activity will be kg/unit of activity data.

⁽³⁾ Use the category also to cover emissions from combined oil and gas production fields. Natural gas processing and distribution from these fields should be included under 1.B.2.b.ii and 1.B.2.b.iii, respectively.

⁽⁴⁾ If using default emission factors these categories will include emissions from production other than venting and flaring.

⁽⁵⁾ If using default emission factors, emissions from Venting and Flaring from all oil and gas production should be accounted for here. Parties using the IPCC software could report those emissions together, indicating so in the documentation box.

⁽⁶⁾ For example, fugitive CO₂ emissions from production of geothermal power could be reported here.

Documentation box:

Gasoline		0.00	0.00	0.00			
Multilateral Operations ⁽¹⁾							

Additional information

Fuel consumption	Allocation ^(a) (percent)	
	Domestic	International
Marine	19.56	80.44
Aviation	34.51	65.49

^(a) For calculating the allocation of fuel consumption, use the sums of fuel consumption by domestic navigation and aviation (Table 1.A(a)) and by international bunkers (Table 1.C).

⁽¹⁾ Parties may choose to report or not report the activity data and emission factors for multilateral operation consistent with the principle of confidentiality stated in the UNFCCC reporting guidelines on inventories. In any case, Parties should report the emissions from multilateral operations, where available, under the Memo Items section of the Summary tables and in the Sectoral report table for energy.

Note: In accordance with the IPCC Guidelines, international aviation and marine bunker fuel emissions from fuel sold to ships or aircraft engaged in international transport should be excluded from national totals and reported separately for informational purposes only.

Documentation box: Please explain how the consumption of international marine and aviation bunkers fuels was estimated and separated from the domestic consumption.

Aviation bunker : the fuel consumption for international aviation is deduced from the balance between the total aviation fuel sale and the estimation of the domestic traffic consumption which is calculated with a detailed approach (based on the individual aircraft movements and using ICAO, MEET and CORINAIR sources of information).

Marine bunker : the UN-ECE definition for international marine traffic is considered. Thus a part from the French bunker is counted within the international marine bunker.

⁽¹⁾ Where the IPCC Guidelines provide options for activity data, e.g. cement or clinker for estimating the emissions from Cement Production, specify the activity data used (as shown in the example in brackets) in order to make the choice of emission factor more transparent and to facilitate comparisons of implied emission factors.

⁽²⁾ Enter cases in which the final emissions are reduced with the quantities of emission recovery, oxidation, destruction, transformation. Adjusted emissions are reported and the quantitative information on recovery, oxidation, destruction, and transformation should be given in the additional columns provided.

⁽³⁾ To avoid double counting make offsetting deductions from fuel consumption (e.g. natural gas) in Ammonia Production, first for feedstock use of the fuel, and then to a sequestering use of the feedstock.

⁽¹⁾ Although shaded, the columns with HFCs and PFCs totals on sheet 1 are kept for consistency with sheet 2 of the table.

⁽²⁾ Note that the units used in this table differ from those used in the rest of the Sectoral report tables, i.e. [t] instead of [Gg].

Note: Where information is confidential the entries should provide aggregate figures but there should be a note indicating this in the relevant documentation boxes of the Sectoral background data tables or as a comment to the corresponding cell.
Gases with GWP not yet agreed upon by the COP, should be reported in Table 9 (Completeness), sheet 2.

⁽³⁾ Potential emissions of each chemical of halocarbons and SF₆ estimated using Tier 1a or Tier 1b of the IPCC Guidelines (Volume 3. Reference Manual, pp. 2.47-2.50). When potential emissions estimates are available in a disaggregated manner corresponding to the subsectors for actual emissions defined on sheet 1 of this table, these should be reported in an annex to sheet 2, using the format of sheet 1, sector F(a). Use Summary 3 of this common reporting format to indicate whether Tier 1a or Tier 1b was used.

⁽⁴⁾ Production refers to production of new chemicals. Recycled substances could be included here, but it should be ensured that double counting of emissions is avoided. Relevant explanations should be provided as a comment to the corresponding cell.

⁽⁵⁾ Relevant just for Tier 1b.

⁽⁶⁾ Sums of the actual emissions of each chemical of halocarbons and SF₆ from the source categories given in sheet 1 of the table multiplied by the corresponding GWP values.

⁽⁷⁾ Potential emissions of each chemical of halocarbons and SF₆ taken from row F(p) multiplied by the corresponding GWP values.

Note: As stated in the revised UNFCCC guidelines, Parties should report actual emissions of HFCs, PFCs and SF₆, where data are available, providing disaggregated data by chemical and source category in units of mass and in CO₂ equivalents. Parties reporting actual emissions should also report potential emissions for the sources where the concept of potential emissions applies, for reasons of transparency and comparability.

⁽¹⁾ Specify the activity data used as shown in the examples within brackets. Where applying Tier 1b (for C), Tier 2 (for E) and country specific methods, specify any other relevant activity data used in the documentation box below.

⁽²⁾ Emissions and implied emission factors are after recovery.

⁽³⁾ Enter cases in which the final emissions are reported after subtracting the quantities of emission recovery, oxidation, destruction, transformation.

Enter these quantities in the specified column and use the documentation box for further explanations.

Note: Where the activity data are confidential, the entries should provide aggregate figures, but there should be a note in the documentation box indicating this.

Documentation box:

HFC and PFC production data are confidential. Only fugitive emissions are available.

⁽¹⁾ Parties should use the documentation box to provide information on the amount of the chemical recovered (recovery efficiency) and other relevant information used in the emission estimation.⁽²⁾ Please click on the button to specify the chemical consumed, as given in the example. If needed, new rows could be added for reporting the disaggregated chemicals from a source by clicking on the corresponding button.

Note: Table 2.(II).F provides for reporting of the activity data and emission factors used to calculate actual emissions from consumption of halocarbons and SF₆ using the "bottom-up approach" (based on the total stock of equipment and estimated emission rates from this equipment). Some Parties may prefer to estimate their actual emissions following the alternative "top-down approach" (based on annual sales of equipment and/or gas). These Parties should provide the activity data used in the current format and any other relevant information in the documentation box at the end of Table 2.(II).F2. Data these Parties should provide includes (1) the amount of fluid used to fill new products, (2) the amount of fluid used to service existing products, (3) the amount of fluid originally used to fill retiring products (the total nameplate capacity of retiring products), (4) the product lifetime, and (5) the growth rate of product sales, if this has been used to calculate the amount of fluid originally used to fill retiring products. Alternatively, Parties may provide alternative formats with equivalent information. These formats may be considered for future versions of the common reporting format after the trial period.

⁽¹⁾ See footnote 4 to Summary 1.A of this common reporting format. Parties which choose to report CO₂ emissions and removals from agricultural soils under 4.D. Agricultural Soils category of the sector Agriculture should indicate the amount [Gg] of these emissions or removals in the documentation box to Table 4.D. Additional information (activity data, implied emissions factors) should also be provided using the relevant documentation box to Table 4.D. This table is not modified for reporting the CO₂ emissions and removals for the sake of consistency with the IPCC tables (i.e. IPCC Sectoral Report for Agriculture).

Note: The IPCC Guidelines do not provide methodologies for the calculation of CH₄ emissions, CH₄ and N₂O removals from agricultural soils, or CO₂ emissions from savanna burning or agricultural residues burning. If you have reported such data, you should provide additional information (activity data and emission factors) used to make these estimates using the relevant documentation boxes of the Sectoral background data tables.

Enteric Fermentation
(Sheet 1 of 1)

France
 1990
 Submission

GREENHOUSE GAS SOURCE AND SINK CATEGORIES	ACTIVITY DATA ⁽¹⁾ AND OTHER RELATED INFORMATION			IMPLIED EMISSION FACTORS
	Population size ⁽²⁾ (1000 head)	Average daily feed intake (MJ/day)	CH ₄ conversion (%)	CH ₄ (kg CH ₄ /head/yr)
1. Cattle	21 724			61.81
Dairy Cattle ⁽³⁾	7 799			82.00
Non-Dairy Cattle	13 925			50.50
2. Buffalo				0.00
3. Sheep	11 554			6.00
4. Goats	1 390			5.00
5. Camels and Llamas				0.00
6. Horses	336			18.00
7. Mules and Asses	13			10.00
8. Swine	6 127			1.00
9. Poultry				0.00
10. Other (please specify) <input type="text"/>				0.00

Additional information (for Tier 2)^(a)

Disaggregated list of animals ^(b)	Dairy Cattle	Non-Dairy Cattle	Other (specify)	
Indicators:				
Weight	(kg)			
Feeding situation ^(c)				
Milk yield	(kg/day)			
Work	(hrs/day)			
Pregnant	(%)			
Digestibility of feed	(%)			

^(a) Compare to Tables A-1 and A-2 of the IPCC Guidelines (Volume 3, Reference Manual, pp. 4.31-4.34). These data are relevant if Parties do not have data on average feed intake.

^(b) Disaggregate to the split actually used. Add columns to the table if necessary.

^(c) Specify feeding situation as pasture, stall fed, confined, open range, etc.

⁽¹⁾ In the documentation boxes to all Sectoral background data tables for Agriculture, Parties should provide information on whether the activity data is one year or a 3-year average.

⁽²⁾ Parties are encouraged to provide detailed livestock population data by animal type and region in a separate table below the documentation box. This consistent set of animal population statistics should be used to estimate CH₄ emissions from enteric fermentation, CH₄ and N₂O from manure management, N₂O direct emissions from soil and N₂O emissions associated with manure production, as well as emissions from the use of manure as fuel, and sewage-related emissions reported in the waste sector.

⁽³⁾ Including data on dairy heifers, if available.

Documentation box:

To calculate methane emissions a specific method based on national expert data (emission factors) is used.
 Activity data is a one year average.

	Other (specify) <input checked="" type="checkbox"/>				0.00	
Boreal					0.00	
			Number of trees (1000s of trees)	Annual growth rate (kt dm/1000 trees)	Carbon uptake factor (t C/tree)	Carbon uptake increment (Gg C)
Non-Forest Trees (specify type)					0.00	0.00
					Total annual growth increment (Gg C)	47 037.55
					Gg CO ₂	172 471.02

	Amount of biomass removed (kt dm)	Carbon emission factor (t C/kt dm)	Carbon release (Gg C)
Total biomass removed in Commercial Harvest	20 170.00	0.50	10 085.00
Traditional Fuelwood Consumed	15 921.00	0.50	7 960.50
Total Other Wood Use		0.00	
Total Biomass Consumption from Stocks ⁽¹⁾ (Gg C)			18 045.50
Other Changes in Carbon Stocks ⁽²⁾ (Gg C)			
		Gg CO ₂	66 166.83

Net annual carbon uptake (+) or release (-) (Gg C)	28 992.05
Net CO ₂ emissions (-) or removals (+) (Gg CO ₂)	106 304.18

⁽¹⁾ Make sure that the quantity of biomass burned off-site is subtracted from this total.⁽²⁾ The net annual carbon uptake/release is determined by comparing the annual biomass growth versus annual harvest, including the decay of forest products and slash left during harvest. The IPCC Guidelines recommend default assumption that all carbon removed in wood and other biomass from forests is oxidized in the year of removal. The emissions from decay could be included under Other Changes in Carbon Stocks.

Note: Sectoral background data tables on Land-Use Change and Forestry should be filled in only by Parties using the IPCC default methodology.

Parties that use country specific methods and models should report information on them in a transparent manner, also providing suggestions for a possible sectoral background data table suitable for their calculation method.

Documentation box:
1) As regards the biomass stock item for the commercial harvest, data are compiled under the 1000 m ³ unit;
2) Consequently to 1), the corresponding average annual growth item is expressed in t dm per annum;

Nitrogen-carbon ratio	0.01	

Note: Sectoral background data tables on Land-Use Change and Forestry should be filled in only by Parties using the IPCC default methodology. Parties that use country specific methods and models should report information on them in a transparent manner, also providing suggestions for a possible sectoral background data table suitable for their calculation method.

Documentation box:

Because of a certain lack of data, the average area converted item was calculated taking into account the 1992-1996 period only. This value was also used to fill in the area converted annually item, as a default value. It is emphasised that the CO₂ emissions due to the grassland conversion are included within item D.5, table 5, since such a conversion is considered as generating CO₂ emissions from soils only, according to the IPCC guidelines. As the French methodology used differs from the IPCC's, a specific document describing it is available at the CITEPA ("Evaluation des puits de CO₂ suivant la nouvelle méthode préconisée par le GIEC", CITEPA, June 1999). The average quantity of biomass left to decay regarding tropical wet vegetation is based on the annual production of harvest.

⁽¹⁾ The information to be reported under Cultivation of Mineral Soils aggregates data per soil type over all land-use/management systems. This refers to land area data and to the emission estimates and implied emissions factors accordingly.

Note: Sectoral background data tables on Land-Use Change and Forestry should be filled in only by Parties using the IPCC default methodology. Parties that use country specific methods and models should report information on them in a transparent manner, also providing suggestions for a possible sectoral background data table suitable for their calculation method.

Documentation Box:

Since the French methodology does not treat the carbon soil release or uptake in relation to the nature of the different soils, a specific document available at the CITEPA ("Evaluation des puits de CO₂ suivant la nouvelle méthode préconisée par le GIEC", CITEPA, June 1999) develops the background processing that leads to the results presented in table 5, section D.5.

MSW - Municipal Solid Waste, SWDS - Solid Waste Disposal Site, MCF - Methane Correction Factor, DOC - Degradable Organic Carbon

(IPCC Guidelines (Volume 3. Reference Manual, section 6.2.4)). MSW includes household waste, yard/garden waste, commercial/market waste and organic industrial solid waste. MSW should not include inorganic industrial waste such as construction or demolition materials.

⁽¹⁾ Actual emissions (after recovery).

⁽²⁾ CH₄ recovered and flared or utilized.

⁽³⁾ Under Waste Disposal. CO₂ emissions should be reported only when the disposed wastes are combusted at the disposal site which might constitute a management practice. CO₂ emissions from non-biogenic wastes are included in the totals, while the CO₂ emissions from biogenic wastes are not included in the totals.

Documentation box:

All relevant information used in calculation should be provided in the additional information box and in the documentation box.

Parties that use country specific models should note this with a brief rationale in the documentation box and fill the relevant cells only.

Table 6A: CH₄ emissions are calculated using a first order decay method based on tier 2.

Table 6C: 15% of the waste incineration CO₂ is considered as from biogenic waste.

Additional information

P = Potential emissions based on Tier 1 approach of the IPCC Guidelines.

A = Actual emissions based on Tier 2 approach of the IPCC Guidelines.

⁽¹⁾ The emissions of HFCs and PFCs are to be expressed as CO₂ equivalent emissions. Data on disaggregated emissions of HFCs and PFCs are to be provided in Table 2(II) of this common reporting format.

⁽²⁾ For verification purposes, countries are asked to report the results of their calculations using the Reference approach and to explain any differences with the Sectoral approach. Where possible, the calculations using the Sectoral approach should be used for estimating national totals. Do not include the results of both the Reference approach and the Sectoral approach in national totals.

⁽³⁾ Other Production includes Pulp and Paper and Food and Drink Production.

Note: The numbering of footnotes to all tables containing more than one sheet continue to the next sheet. Common footnotes are given only once at the first point of reference.

	0.00														

⁽⁴⁾ According to the IPCC Guidelines (Volume 3. Reference Manual, pp. 4.2, 4.87), CO₂ emissions from agricultural soils are to be included under Land-Use Change and Forestry (LUCF). At the same time, the Summary Report 7A (Volume 1. Reporting Instructions, Tables.27) allows for reporting CO₂ emissions or removals from agricultural soils, either in the Agriculture sector, under D. Agricultural Soils or in the Land-Use Change and Forestry sector under D. Emissions and Removals from Soil. Parties may choose either way to report emissions or removals from this source in the common reporting format, but the way they have chosen to report should be clearly indicated, by inserting explanatory comments to the corresponding cells of Summary 1.A and Summary 1.B. Double-counting of these emissions or removals should be avoided. Parties should include these emissions or removals consistently in Table8(a) (Recalculation - Recalculated data) and Table10 (Emission trends).

⁽⁵⁾ Please do not provide an estimate of both CO₂ emissions and CO₂ removals. "Net" emissions (emissions - removals) of CO₂ should be estimated and a single number placed in either the CO₂ emissions or CO₂ removals column, as appropriate. Please note that for the purposes of reporting, the signs for uptake are always (-) and for emissions (+).

⁽⁶⁾ Note that CO₂ from Waste Disposal and Incineration source categories should only be included if it stems from non-biogenic or inorganic waste streams.

CO₂ Emissions from Biomass	37 858.66														

P = Potential emissions based on Tier 1 approach of the IPCC Guidelines.

A = Actual emissions based on Tier 2 approach of the IPCC Guidelines.

⁽¹⁾ The emissions of HFCs and PFCs are to be expressed as CO₂ equivalent emissions. Data on disaggregated emissions of HFCs and PFCs are to be provided in Table 2(II) of this common reporting format.

⁽²⁾ For verification purposes, countries are asked to report the results of their calculations using the Reference approach and to explain any differences with the Sectoral approach in document box of Table 1.A(c). Where possible, the calculations using the Sectoral approach should be used for estimating national totals. Do not include the results of both the Reference approach and the Sectoral approach in national totals.

⁽³⁾ See footnote 4 to Summary 1.A.

⁽⁴⁾ Please do not provide an estimate of both CO₂ emissions and CO₂ removals. "Net" emissions (emissions - removals) of CO₂ should be estimated and a single number placed in either the CO₂ emissions or CO₂ removals column, as appropriate. Please note that for the purposes of reporting, the signs for uptake are always (-) and for emissions (+).

SUMMARY 2 SUMMARY REPORT FOR CO₂ EQUIVALENT EMISSIONS

G. Other												

⁽¹⁾ Use the following notation keys to specify the method applied: D (IPCC default), RA (Reference Approach), T1 (IPCC Tier 1), T1a, T1b, T1c (IPCC Tier 1a, Tier 1b and Tier 1c, respectively), T2 (IPCC Tier 2), T3 (IPCC Tier 3), C (CORINAIR), CS (Country Specific), M (Model). If using more than one method, enumerate the relevant methods. Explanations of any modifications to the default IPCC methods, as well as information on the proper use of methods per source category where more than one method is indicated, and explanations on the country specific methods, should be provided in the documentation box of the relevant Sectoral background data table.

⁽²⁾ Use the following notation keys to specify the emission factor used: D (IPCC default), C (CORINAIR), CS (Country Specific), PS (Plant Specific), M (Model). Where a mix of emission factors has been used, use different notations in one and the same cells with further explanation in the documentation box of the relevant Sectoral background data table.

⁽¹⁾ This table is intended to be used by Parties to summarize their own assessment of completeness (e.g. partial, full estimate, not estimated) and quality (high, medium, low) of major source/sink inventory estimates. The latter could be understood as a quality assessment of the uncertainty of the estimates. This table might change once the IPCC completes its work on managing uncertainties of GHG inventories. The title of the table was kept for consistency with the current table in the IPCC Guidelines.

Note: To fill in the table use the notation key as given in the IPCC Guidelines (Volume 1. Reporting Instructions, Tables. 37).

Sources and sinks not reported (NE) ⁽¹⁾				
GHG	Sector ⁽²⁾	Source/sink category ⁽²⁾	Explanation	
CO ₂				
CH ₄	1A3. Transport	Civil Aviation	neglected	
	1A3 Transport	Marine national / international	neglected	
N ₂ O	4D. Agricultural Soils	Atmospheric Deposition	not included because of possible double counting	
	1A3. Transport	Civil Aviation	neglected	
HFCs				
PFCs				
SF ₆	2. Industrial process	Consumption of SF ₆ from various minor applications (window insulation, tennis balls etc.) - neglected		
Sources and sinks reported elsewhere (IE) ⁽³⁾				
GHG	Source/sink category	Allocation as per IPCC Guidelines	Allocation used by the Party	Explanation
CO ₂	1A2a-e		1A2f	Not available in the national inventory database at this time
CH ₄	1A2a-e		1A2f	Not available in the national inventory database at this time
N ₂ O	1A2a-e		1A2f	Not available in the national inventory database at this time
HFCs				
PFCs				
SF ₆				

⁽¹⁾ Please, clearly indicate sources and sinks which are considered in the IPCC Guidelines but are not considered in the submitted inventory. Explain the reason for excluding these sources and sinks, in order to avoid arbitrary interpretations. An entry should be made for each source/sink category for which the indicator "NE" is entered in the sectoral tables.

⁽²⁾ Indicate omitted source/sink following the IPCC source/sink category structure (e.g. sector: Waste, source category: Wastewater Handling).

⁽³⁾ Please clearly indicate sources and sinks in the submitted inventory that are allocated to a sector other than that indicated by the IPCC Guidelines. Show the sector indicated in the IPCC Guidelines and the sector to which the source or sink is allocated in the submitted inventory. Explain the reason for reporting these sources and sinks in a different sector. An entry should be made for each source/sink for which the indicator "IE" is used in the sectoral tables.

 Submission

Additional GHG emissions reported ⁽⁴⁾						
GHG	Source category	Emissions (Gg)	Estimated GWP value (100-year horizon)	Emissions CO ₂ equivalent (Gg)	Reference to the data source of GWP value	Explanation

⁽⁴⁾ Parties are encouraged to provide information on emissions of greenhouse gases whose GWP values have not yet been agreed upon by the COP. Please include such gases in this table if they are considered in the submitted inventory. Provide additional information on the estimation methods used.

1 - INTRODUCTION

La connaissance des quantités de certaines substances rejetées dans l'atmosphère est une étape nécessaire et fondamentale à toute politique de protection de l'Environnement qui s'intéresse aux problèmes actuels comme l'acidification, la dégradation de la qualité de l'air, le réchauffement global et les modifications du climat, l'appauvrissement de la couche d'ozone stratosphérique, etc.

Cette quantification que l'on dénomme usuellement "inventaire d'émission" s'effectue à partir de règles spécifiques qui varient éventuellement d'un inventaire à l'autre.

Cet état de fait présente l'énorme désavantage de ne pouvoir disposer de données comparables. A l'échelon international des travaux d'harmonisation sont engagés depuis plusieurs années entre DIVERS ORGANISMES INTERNATIONAUX (Commission Européenne, Commission Economique pour l'Europe des Nations Unies, Groupe Intergouvernemental sur l'Evolution du Climat [GIEC, IPCC en anglais], EUROSTAT, Agence Internationale de l'Energie, etc.). Ces travaux se poursuivent conjointement à l'amélioration des méthodologies permettant d'estimer les rejets de divers types d'émetteurs.

Pour tenir compte des changements de spécifications et de l'amélioration dans la connaissance des phénomènes sources de pollution atmosphérique, les résultats des inventaires d'émissions doivent donc être régulièrement révisés y compris rétrospectivement afin de maintenir des séries cohérentes.

Le CITEPA qui remplit la fonction de Centre National de Référence a développé un système d'inventaires dans le cadre du programme CORALIE (COordinarion de la RéALisation des Inventaires d'Emissions) avec le concours financier du Ministère chargé de l'Aménagement du Territoire et de l'Environnement (MATE).

Ce système d'inventaire est à la base fortement inspiré des principes de CORINAIR (voir encart suivant). Il vise à optimiser les efforts importants de collecte, de traitement et de restitution des informations, d'autant que de multiples demandes d'inventaires ayant chacune des spécifications différentes doivent être satisfaites (voir figure 1).

Les principes de la méthodologie employée sont décrits de manière synthétique dans les sections qui suivent.

Inventaire d'émission

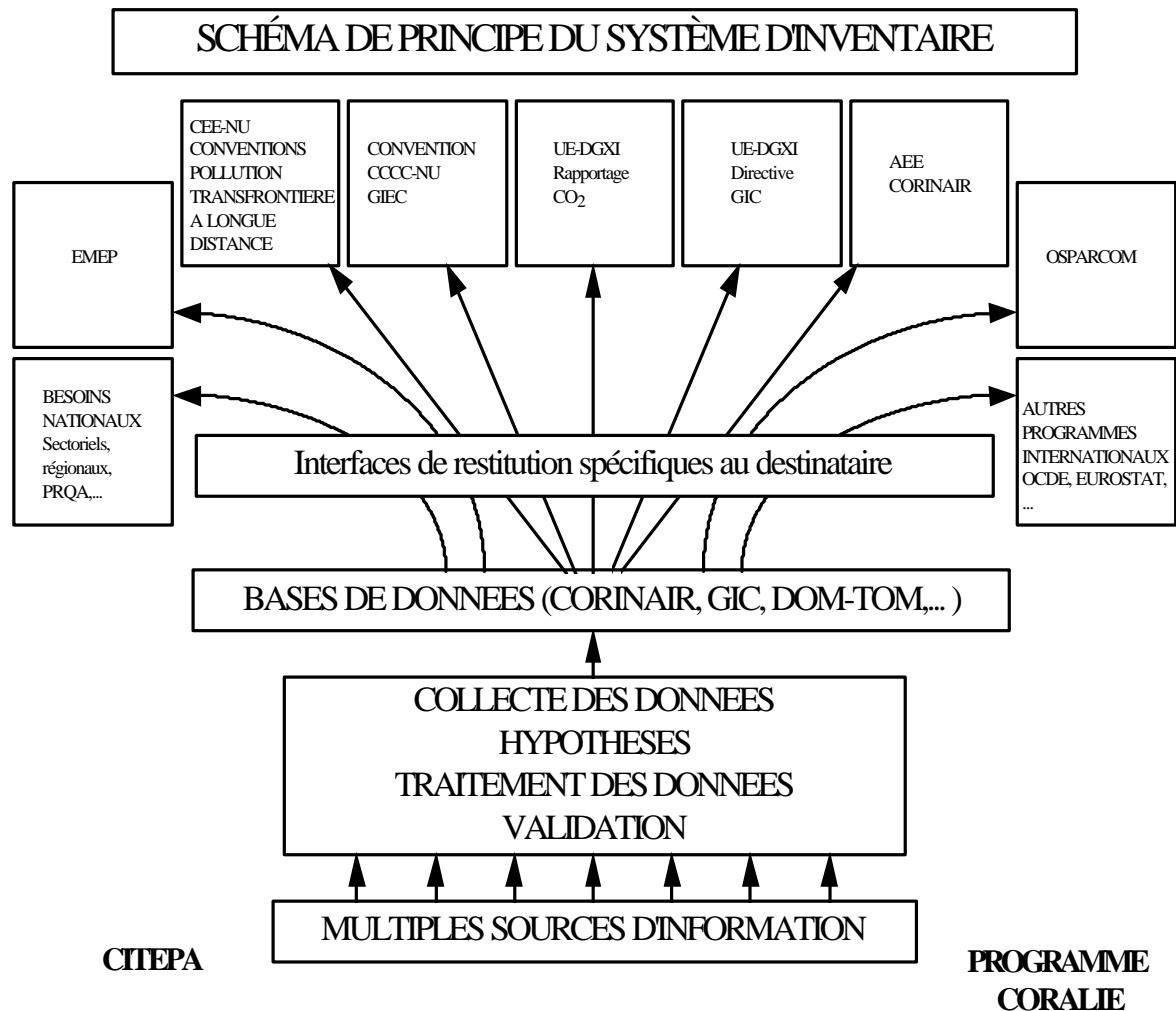

C'est la description qualitative et quantitative des rejets de certaines substances dans l'atmosphère issus de sources anthropiques et/ou naturelles.

Un inventaire d'émission doit présenter les qualités suivantes :

- complet : toutes les sources doivent être prises en compte et les émissions renseignées,
- cohérence : la série obtenue sur la période étudiée doit être homogène, impliquant des méthodes identiques et des données homogènes
- comparabilité : l'inventaire doit être réalisé au moyen d'une méthodologie reconnue et documentée, afin d'assurer la comparabilité des résultats,
- traçabilité : les informations fournies doivent être suffisamment détaillées pour permettre à un tiers de reconstruire les émissions.

Ces qualités facilitent les opérations de validation et de vérification qui consistent à respectivement vérifier que l'inventaire a été réalisé conformément à la méthodologie annoncée et s'assurer que les émissions obtenues reflètent, à peu près bien la réalité.

FIGURE 1

CORINAIR

La méthodologie CORINAIR a été initialement développée dans le cadre du programme CORINE lancé par la Commission des Communautés Européennes en 1985. Son nom provient de la contraction du nom de ce programme et du domaine d'intérêt relatif à la réalisation d'inventaires d'émissions de polluants dans l'air (CORINE-AIR).

Ces travaux se sont ensuite poursuivis à l'initiative du Comité chargé de préparer la mise en place de l'Agence Européenne de l'Environnement, puis de cette dernière à part entière dès qu'elle fut opérationnelle en 1994.

Pour assurer cette tâche, l'Agence Européenne de l'Environnement s'est entourée d'un Centre Thématisque Européen des Emissions dans l'Air qui comporte plusieurs institutions : UBA (Allemagne - chef de projet), AEA Technology (Royaume-Uni), RISØ (Danemark), ENEA (Italie), CITEPA (France), UBA (Autriche), TNO (Pays-Bas), POSEIDON (Grèce). Le Centre Thématisque des Emissions dans l'Air est en charge du développement du système CORINAIR dont de nombreux éléments constituent des "standards" européens.

Trois inventaires CORINAIR ont été réalisés :

- CORINAIR 85 : SO₂, NOx, COV au sein des 12 Etats membres de la Communauté Européenne.
- CORINAIR 90 : SO₂, NOx, COVNM, CH₄, CO, CO₂, N₂O, NH₃ pour 29 pays d'Europe.
- CORINAIR 94 : 27 substances (9 métaux lourds et 10 composés organiques persistants ajoutés à la liste précédente) pour une vingtaine de pays.

Les trois inventaires CORINAIR ci-dessus ont une résolution géographique fine et sont basés sur des catégories de sources assez détaillées.

La méthodologie CORINAIR permet de réaliser des inventaires compatibles avec les spécifications requises par la CEE-NU, l'EMEP, la CCCC-NU, OSPARCOM, le Mécanisme Communautaire de surveillance du CO₂, etc.

Actuellement l'inventaire CORINAIR (rebaptisé CORe INventory AIR) s'identifie avec les inventaires annuels réalisés pour les protocoles de la convention des Nations-unies sur la pollution transfrontalière à longue distance au niveau national et des travaux sont également en cours dans le cadre des inventaires d'émission intégrés.

2 – PRINCIPES ET DEFINITIONS

Cette section présente la méthodologie suivie et passe en revue les principales hypothèses et données utilisées après avoir rappelé les spécifications des inventaires.

2.1 / méthodologie

La méthodologie CORINAIR qui s'est développée depuis le milieu des années 80, vise à obtenir des inventaires offrant les qualités fondamentales indispensables : cohérents, complets, comparables, transparents (voir encart dans la section précédente). Elle se base sur les éléments décrits brièvement ci-après.

2.1.1 / substances étudiées

Les substances étudiées varient selon les inventaires. Au total, 26 substances sont actuellement étudiées, à savoir les 8 substances SO₂, (SO₂ + SO₃), NOx (NO + NO₂), COVNM (Composés Organiques Volatils totaux non méthaniques), CH₄, CO, CO₂, N₂O, NH₃, auxquelles s'ajoutent les trois gaz à effet de serre introduits à Kyoto (HFC, PFC et SF₆), 9 métaux lourds, et 6 produits organiques persistants (POP). Les poussières totales et les particules fines sont en cours d'intégration.

Toutes les émissions sont estimées en masse de substance sous la forme chimique citée (exemple NH₃ en tonnes de NH₃ et non de N). Cependant, il y a lieu de préciser les points suivants :

- Le terme NOx couvre exclusivement le monoxyde et le dioxyde d'azote. Les émissions sont exprimées en équivalent NO₂. Le N₂O, autre composé oxygéné de l'azote, est considéré séparément.
- Sous l'acronyme COVNM, les composés organiques volatils sont considérés globalement, le méthane étant exclus; ce dernier étant comptabilisé séparément. Aucun composé particulier n'est différencié à l'exception des produits organiques persistants cités ci-dessus. Les émissions correspondent à la somme des émissions de corps chimiquement différents. Le système d'inventaire comporte une spéciation des COVNM en environ 250 espèces ou familles de composés qui permet d'estimer des émissions de ces composés.
- Par convention, les émissions de CO₂ sont exprimées en CO₂ ultime, c'est-à-dire que le carbone émis sous d'autres formes chimiques (CO, CH₄, COVNM, etc.) est assimilé à du CO₂ à quelques exceptions près.

Par ailleurs, on notera que, toujours par convention, le CO₂ total est présenté sous la forme d'émissions nettes, c'est-à-dire que les puits de CO₂ (par exemple, la photosynthèse) viennent en déduction des émissions. A cet effet, les inventaires distinguent les sources et les puits. Cependant, certains phénomènes naturels supposés être en équilibre quant au bilan de CO₂, comme les respirations humaine et animale, ne sont pas inclus dans l'inventaire bien qu'ils représentent des flux de CO₂ très significatifs au regard des émissions totales nettes (environ 1/3).

Le niveau de détail considéré dans le système permet de produire des indicateurs relatifs à des synergies entre substances tels que l'indicateur acide équivalent (Aeq) pour SO₂, NOx et NH₃ et le pouvoir de réchauffement global (PRG) pour CO₂, CH₄, N₂O, HFC, PFC, SF₆.

2.1.2 / nomenclatures des sources émettrices

Les activités anthropiques ou naturelles à l'origine des rejets de diverses substances dans l'atmosphère sont identifiées dans une nomenclature de référence appelée SNAP (Selected Nomenclature for Air Pollution). Cette nomenclature qui constitue un standard européen, voire international, évolue dans le temps en fonction des substances retenues par le programme CORINAIR de l'Agence Européenne de l'Environnement et des améliorations apportées.

Actuellement et dans le cas de l'inventaire faisant l'objet du présent rapport, la nomenclature utilisée est la SNAP 97 qui couvre les 30 substances couvertes par CORINAIR (voir plus loin).

Bien que ne prétendant pas à l'exclusivité, la SNAP 97 présente une liste détaillée d'activités (près de 400 items pour la résolution la plus fine). Quelques items, "autres" permettent d'inclure le cas échéant des activités supplémentaires (activités omises ou plus généralement négligées du fait de leurs très faibles contributions).

La SNAP 97 est structurée en trois niveaux dont certains constituent le format de rapport des données d'inventaires.

Dans le cas des activités mettant en œuvre une combustion, la définition de l'activité émettrice est généralement affinée en distinguant les différents combustibles utilisés. La nomenclature correspondante baptisée NAPFUE (Nomenclature for Air Pollution of FUEls) prévoit dans sa version 1994, 59 types de combustibles différents.

Le système utilisé prévoit une décomposition de chaque activité le cas échéant. Cette opportunité est utilisée, par exemple, pour différencier certains procédés, apprécier des tailles d'équipements, etc.. Pour ce faire, des rubriques peuvent être ajoutées à l'activité lors de la construction de l'inventaire.

La combinaison de ces trois composantes (activité, combustible, rubrique) qui est détaillée à la section 1.6, constitue l'ensemble des activités émettrices élémentaires qui peut donc comporter plusieurs milliers d'éléments selon le degré de résolution retenu pour l'inventaire. Actuellement, pour les inventaires relatifs à la France on dénombre de l'ordre de 500 activités élémentaires.

2.1.3 / types de sources

Plusieurs catégories de sources de rejets atmosphériques sont considérées par la méthodologie d'inventaire. Toutefois, selon les cas ces catégories peuvent exister ou non.

- Sources Ponctuelles

Une source ponctuelle correspond typiquement à une installation fixe telle qu'une usine.

- Sources linéaires

Elles sont essentiellement constituées par les principaux axes de communication (routier, fluvial, maritime, etc.). Elles sont donc le plus souvent relatives aux sources mobiles et occasionnellement aux sources fixes (gazoduc, oléoduc, etc.).

- Grandes Sources Ponctuelles (GSP)

Il s'agit des sources fixes canalisées ou diffuses dont les rejets potentiels ou effectifs dans l'atmosphère excèdent certains seuils.

Ces seuils constituent une spécification propre à chaque inventaire et résultent de multiples paramètres (objectifs de l'inventaire, zone étudiée, substances considérées, ressources et délai consacrés à l'inventaire).

- Grandes Sources Linéaires (GSL)

De manière analogue aux GSP, elles regroupent des tronçons de route à fort trafic dont les niveaux d'émissions sont comparables à ceux atteints par des émetteurs ponctuels (autoroute, route nationale, etc.)

- Sources surfaciques (SUR)

Cette catégorie couvre, le solde des sources constitué par, d'une part, les sources fixes non incluses dans la catégorie des Grandes Sources Ponctuelles et, d'autre part, les sources fixes et mobiles non incluses dans les Grandes Sources Linéaires. On y trouve typiquement la circulation urbaine diffuse, l'habitat, les espaces cultivés, etc.).

Cette classification vise à renforcer la fiabilité des estimations et procure des informations plus appropriées à certains besoins (par exemple la modélisation de la qualité de l'air). En effet, pour certaines substances comme le SO₂ on observe qu'une part importante des émissions provient d'un nombre limité de sources. C'est pourquoi, la méthodologie suivie pour la réalisation de certains inventaires est basée sur une approche individualisée des Grandes Sources Ponctuelles et/ou Linéaires.

2.1.4 / couverture et résolution spatiale

Cette spécification varie d'un inventaire à l'autre. Dans le cas de la France on dénombre au moins trois cas différents obtenus par combinaison des entités « métropole », « départements d'outre-mer (DOM) » et « Territoires d'outre-mer (TOM) » selon la couverture géographique propre à chaque inventaire.

La résolution spatiale porte généralement :

- d'une part, globalement sur la France métropolitaine et dans certains cas l'outre-mer pour satisfaire les demandes annuelles générales.
- d'autre part, sur une résolution correspondant à des entités administratives plus petites (régions, départements, arrondissements, unités urbaines, zones de 50 x 50 km² voire moins, etc.). Les inventaires de résolution spatiale plus élevée ne sont généralement réalisés que périodiquement (par exemple tous les cinq ans en ce qui concerne l'inventaire pour l'EMEP¹).

2.1.5 / étendue et résolution temporelle

Sauf cas particulier, les inventaires sont établis sur la base d'une année civile sans distinction de périodes particulières (saison, semaine, etc.). Des profils temporels sont parfois disponibles pour évaluer la répartition des émissions dans le temps.

¹ European Monitoring and Evaluation Programme

2.2 / principes méthodologiques

Les émissions sont estimées pour chacune des activités émettrices élémentaires retenues pour l'inventaire (cf. section 2.1.2) en considérant séparément s'il y a lieu les différentes catégories de sources (surfaciques, grandes sources ponctuelles et grandes sources linéaires).

Les émissions d'une activité donnée sont exprimées par la formule générale et schématique suivante :

$$E_{s,a,t} = A_{a,t} \times F_{s,a} \quad (1)$$

avec E : émission relative à la substance "s" et à l'activité "a" pendant le temps "t"
 A : quantité d'activité relative à l'activité "a" pendant le temps "t"
 F : facteur d'émission relatif à la substance "s" et à l'activité "a".

Pour l'ensemble des activités, les émissions totales sont exprimées par la formule suivante :

$$E_{s,t} = \sum_{a=1}^{a=n} E_{s,a,t}$$

avec n : nombre d'activités émettrices prises en compte.

Il est évident que si la valeur de n diffère d'un inventaire à un autre (ce qui est souvent le cas), les émissions totales peuvent ne plus être comparables (inventaires à champs non constants) et les contributions relatives des sources varier.

Les termes $A_{a,t}$ et $F_{s,a}$ dans la formule (1) sont en fait déterminés pour des combinaisons plus fines de l'activité associant de manière générale une opération, une technologie et un produit.

Exemples :

- fabriquer de la chaleur au moyen d'une chaudière de 50 MW équipée d'un brûleur bas NOx fonctionnant au fioul lourd
- se déplacer en voiture particulière équipée d'un moteur à essence de 2 l de cylindrée.

Cette description est illustrée par la formule ci-après pour une substance, un intervalle de temps et une entité géographique donnés.

$$E_{s,t,z} = \sum_{a,i,f} \left[A_{a,i,f,t,z} \times \sum_p \left[F_{s,a,i,f,p} \times P_{a,i,f,p} \right] \right] \quad (2)$$

avec :

- A : quantité d'activité
- F : facteur d'émission,
- P : fraction de secteur, d'activité, de combustible et de procédé,
- a : indice relatif au type de source,
- f : indice relatif au type de combustible
- i : indice relatif au secteur économique
- p : indice relatif au procédé,
- s : indice relatif à la substance,
- t : indice relatif à l'intervalle de temps,
- z : indice relatif à l'entité géographique.

Dans certains cas, les émissions présentent des relations complexes avec de nombreux paramètres caractéristiques et il est alors nécessaire de recourir à des modèles spécifiques pour obtenir une bonne représentation des phénomènes. C'est le cas du trafic routier, des émissions biogènes, etc.

In fine, il sera toujours possible de se ramener à une expression de la forme de l'équation (1) en rapportant les émissions à un seul paramètre relatif à l'activité. Cette représentation d'une simplicité extrême, qui masque la structure réelle et éventuellement complexe des émissions de l'activité, peut conduire à des interprétations erronées.

Les Grandes Sources (Ponctuelles et Linéaires) sont étudiées individuellement ; on bénéficie des émissions de certaines substances qui sont mesurées en permanence ou à intervalles réguliers sur certaines installations. D'autres méthodes telles que des corrélations entre les paramètres caractéristiques d'un procédé et les émissions, ainsi que des bilans permettent de connaître les rejets spécifiques de la source considérée pour certaines substances. Les formules (1) et (2) ne sont alors utilisées qu'en tout ou partie.

Pour certaines substances (SO_2 , NO_x , CO , CO_2 , etc.), une part importante des émissions est liée à l'utilisation de l'énergie.

Pour l'application de la formule (2), on peut expliciter les rejets en exprimant les émissions totales d'une source comme étant égales à la somme de deux émissions distinctes (en pratique, réelles ou virtuelles selon les cas).

$$E = E_1 + E_2$$

avec :

E_1 : émission liée à la combustion d'énergie fossile et de biomasse.

E_2 : émission liée à d'autres phénomènes se rapportant à l'emploi de matières premières, à des réactions, à des opérations diverses (évaporation, broyage, réaction chimique, etc.).

Selon les valeurs prises respectivement par E_1 et E_2 , six cas sont à considérer (voir figure 2) :

$E_1 = 0$ et $E_2 < 0$	procédé constituant un puits (émission négative, comme la photosynthèse pour le CO_2).
$E_1 > 0$ et $E_2 < 0$	procédé avec combustion et rétention.
$E_1 = E_2 = 0$	procédé ne contribuant pas à la pollution atmosphérique ou dont la contribution est négligeable.
$E_1 = 0$ et $E_2 > 0$	procédé sans rapport avec l'utilisation de l'énergie ; les émissions proviennent de réactions chimiques, d'actions mécaniques comme le broyage, d'évaporations de produits, etc.
$E_1 > 0$ et $E_2 = 0$	combustion dans des procédés où il n'y a pas contact entre la flamme ou les produits de combustion et un produit tiers (e.g. combustion sous chaudière, moteurs, etc.).
E_1 et $E_2 > 0$	procédé impliquant une combustion associée à d'autres phénomènes, notamment ceux où il y a contact entre une matière première ou un produit et une flamme ou les produits de la combustion (par exemple fours).

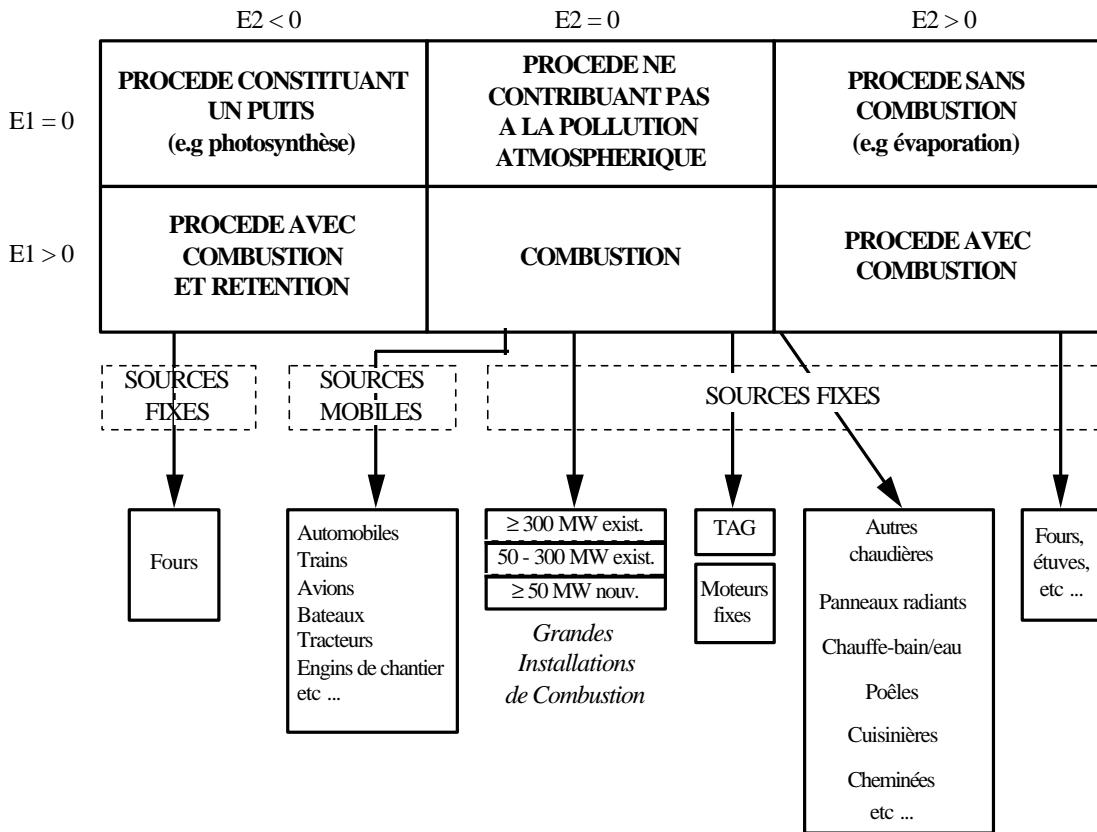

Des différenciations plus fines conduisent à une caractérisation de certaines sources (cf. fig. 2).

La formule (2) s'applique, en principe, à toute entité géographique z.

L'accessibilité à la quantité d'activité $A_{a,i,f,t}$ est d'autant plus difficile que la zone géographique se restreint : le plus souvent l'information recherchée n'existe pas à ce niveau ou est confidentielle.

Il y a lieu de remarquer que la quantité d'informations à collecter et à gérer ainsi que l'incertitude relative à l'information élémentaire augmentent considérablement avec la résolution spatio-temporelle.

Figure 2 : Typologie des sources au regard de l'utilisation de l'énergie

Il est suppléé à l'indisponibilité de certaines informations à différents niveaux géographiques (donnée inexiste, confidentialité, etc.), en établissant une relation avec des paramètres socio-économiques disponibles (population, emploi, superficie, etc.). La quantité d'activité d'une entité géographique de niveau $n + 2$ est estimée à partir de la quantité d'activité connue ou estimée au niveau $n + 1$ (qui peut elle-même être déduite du niveau n , etc.). Cette dernière est répartie au moyen des relations supplémentaires établies spécifiquement pour cette activité selon les formules suivantes (cf. figure 3).

Pour une entité géographique z_n de niveau N , constituée de j entités géographiques z_{n+1} de niveau plus fin $N + 1$ on a :

$$A_{a,i,f,z_n} = \sum_j A_{a,i,f,z_{n+1}}$$

$$A_{a,i,f,z_{n+1}} = K_{zi,n+1} \times \left(A_{a,i,f,z_n} - \sum_j A_{a,i,f,zc_{n+1}} \right)$$

avec :

- zi entité géographique pour laquelle la quantité d'activité relative à a,i,f est inconnue.
- zc entité géographique pour laquelle la quantité d'activité relative à a,i,f est connue.
- j nombre d'entités géographiques de niveau $n + 1$ pour lesquelles la quantité d'activité relative à a,i,f est connue.

et :

$$K_{zi_{n+1}} = \frac{\mathbf{a}_a \times P_{1,a,zi_{n+1}} + \mathbf{b}_a \times P_{2,a,zi_{n+1}} + \mathbf{g}_a \times P_{3,a,zi_{n+1}} + \dots}{\sum_{zi_{n+1}} (\mathbf{a}_a \times P_{1,a} + \mathbf{b}_a \times P_{2,a} + \mathbf{g}_a \times P_{3,a} + \dots)}$$

avec :

$P_{1,a}, P_{2,a}, P_{3,a}, \dots$ paramètres socio-économiques associés à l'activité a

$\mathbf{g}_a, \mathbf{b}_a, \mathbf{g}_a, \dots$ coefficients de pondération associés aux paramètres socio-économiques pour l'activité a avec $\mathbf{a} + \mathbf{b} + \mathbf{g} = 1$ et $0 \leq \mathbf{a}, \mathbf{b}, \mathbf{g} \leq 1$

Certains paramètres socio-économiques pouvant eux-mêmes être indisponibles à certains niveaux géographiques, chaque activité peut-être associée à différentes relations supplémentaires classées selon un ordre hiérarchique de pertinence.

Le système utilisé jusqu'à présent limite à trois le nombre de paramètres socio-économiques utilisés dans une même relation supplémentaire. Ceci n'est pas une limite de principe, mais s'avère généralement largement suffisant en pratique.

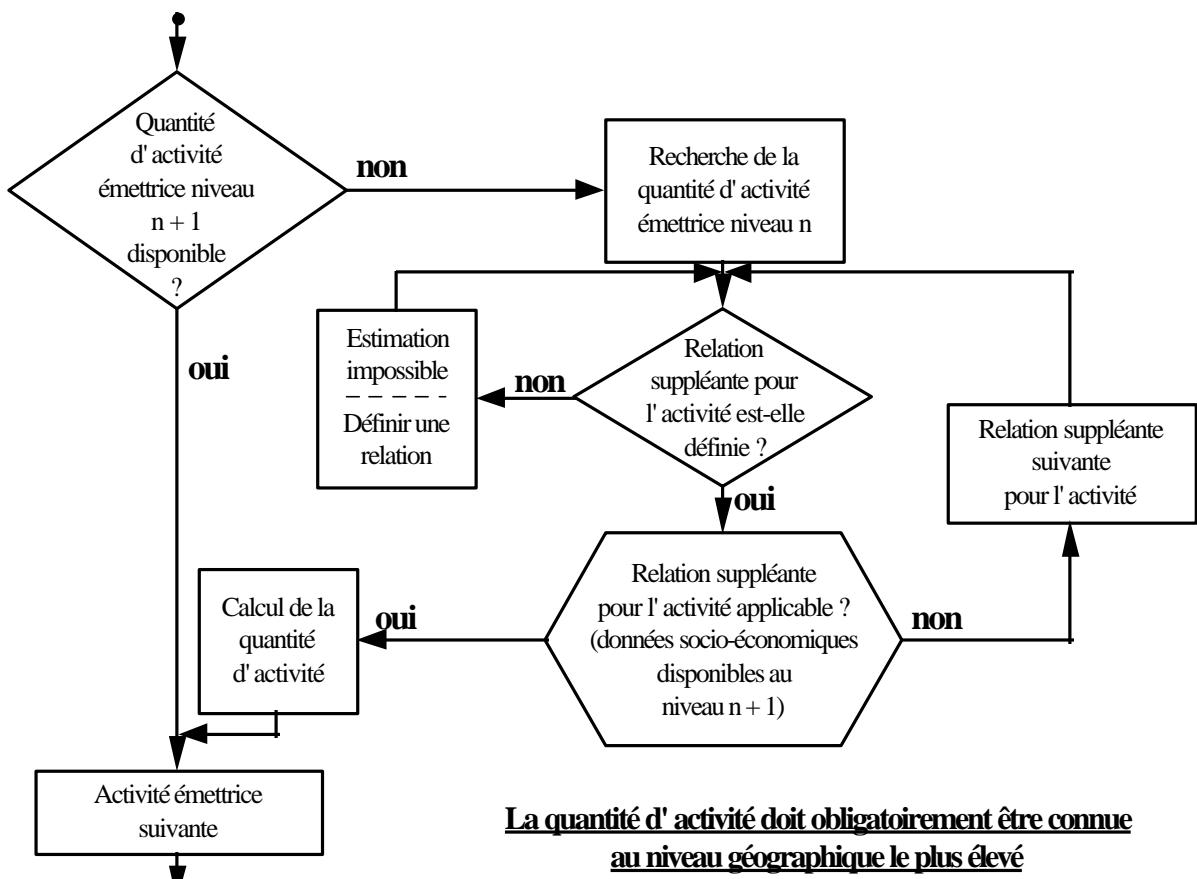

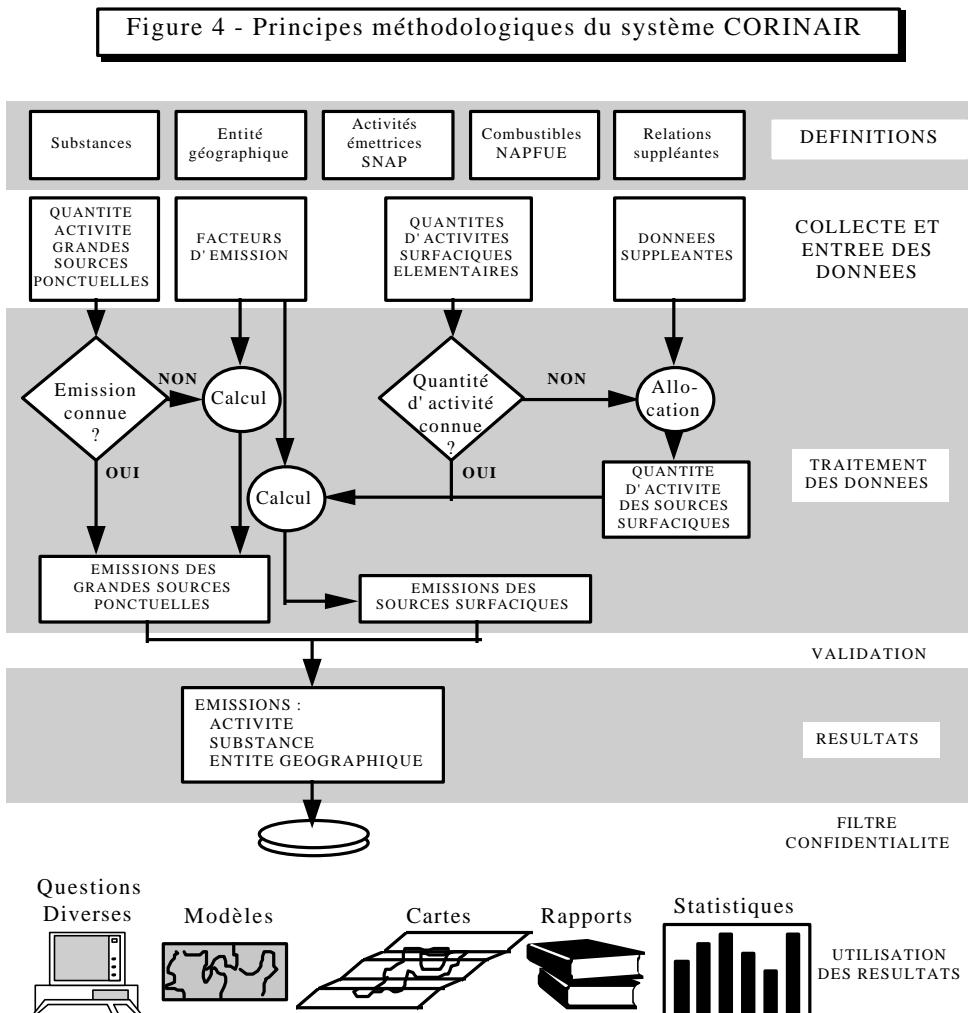

Figure 3 : Estimation des quantités d'activité non disponibles

La figure 4 représente schématiquement l'ensemble du système d'inventaire.

3 – HYPOTHESES, DONNEES DE BASE ET ELEMENTS METHODOLOGIQUES

Cette section présente les principales hypothèses retenues pour construire l'inventaire ainsi que l'origine des sources d'information les plus importantes et fournit des éléments méthodologiques relatifs aux estimations des émissions.

La méthodologie utilisée dans les inventaires d'émissions est dite "**orientée source**". Cela signifie que **les émissions sont localisées géographiquement et par secteurs là où elles sont réellement rejetées**. En conséquence, à titre d'exemple, l'utilisation de l'électricité correspond à une émission nulle, les émissions étant attribuées à l'entité de production.

3.1 / procédés liés à l'utilisation de l'énergie fossile et de la biomasse

Seuls, les combustibles fossiles et la biomasse sont pris en compte au regard des substances étudiées dans le présent inventaire.

L'extraction, la transformation, le transport, la distribution de produits énergétiques et l'utilisation de combustibles fossiles et de la biomasse à des fins énergétiques engendrent des rejets de nombreuses substances dans l'atmosphère et constituent pour nombre d'entre elles une contribution majeure (SO_2 , NOx , CO , CO_2 , métaux lourds, etc.). Avec la méthodologie employée, qui prend en compte à la fois des données individuelles et sectorielles, il est particulièrement important de reconstruire un bilan énergétique en adéquation avec les données nationales officielles établies par l'Observatoire de l'Energie.

Les quantités de combustibles fossiles et de biomasse utilisées dans des installations de combustion sont des données de base indispensables. Une part importante est connue sur une base individuelle par l'intermédiaire de diverses enquêtes (EACEI², taxe sur les émissions atmosphériques, inventaire des Grandes Installations de Combustion, enquête auprès des industriels). Une autre part est disponible pour certains secteurs, certains combustibles, certains équipements, certaines entités géographiques (industrie, chauffage urbain, transports routiers, etc.). Enfin, on dispose du bilan énergétique national de l'Observatoire de l'Energie qui sert de référence. Pour apprécier les pressions sur l'Environnement, il est nécessaire de connaître les consommations d'énergie selon un découpage assez fin des combustibles : en effet, par exemple, le fioul lourd et le gaz de pétrole liquéfié n'émettent pas les mêmes quantités de SO_2 , NOx , COV , CO_2 , etc. rapportées à une même unité d'énergie, que les produits pétroliers dans leur ensemble, lesquelles émissions dépendent aussi du procédé considéré et des éventuels équipements de dépollution voire des conditions opératoires dans certains cas. Toutes ces données sont mises en relation et segmentées, de manière appropriée (cf. figure 5).

L'objectif de l'inventaire étant de fournir une représentation des émissions aussi proche que possible de la réalité, les informations utilisées sont systématiquement des données **non corrigées du climat**, bien que des données corrigées du climat aient par ailleurs un intérêt pour l'étude des évolutions à moyen et long termes.

Les émissions sont déterminées :

- soit au moyen des résultats de mesures en continu ou périodiques effectuées au niveau du rejet des émetteurs, de corrélations ou de bilans spécifiques pour les émetteurs les plus importants et certaines substances (SO_2 , NOx , métaux lourds, etc.),
- soit au moyen de coefficients appelés facteurs d'émissions tenant compte de la nature des procédés mis en œuvre lorsque le cas ci-dessus n'est pas applicable.

3.1.1 / extraction, transport, distribution d'énergie fossile

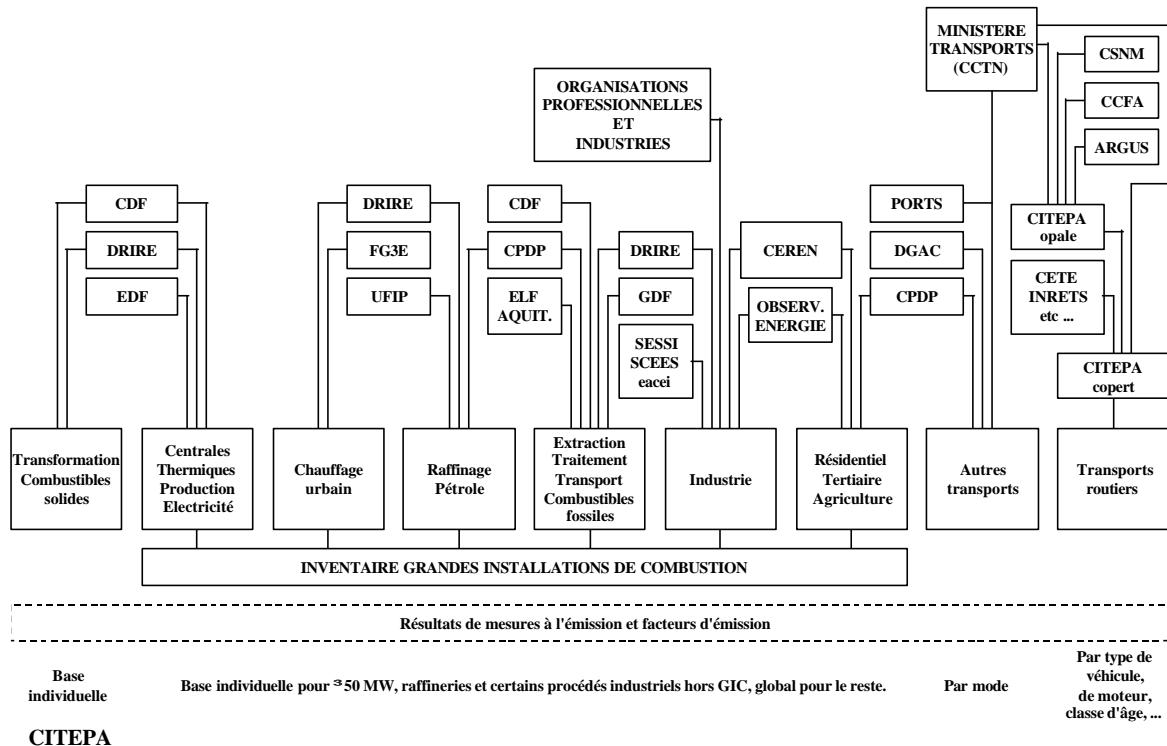

Pour les Combustibles Minéraux Solides (CMS), les données sont issues du bilan charbonnier. La production nationale de CMS est en régulière diminution. Les bassins encore exploités (Lorraine et Provence notamment) ne couvrent qu'une petite partie des besoins, le solde étant assuré par les importations..

L'extraction et la distribution du charbon des mines grisouteuses est à l'origine d'émissions fugitives de méthane. La part du rejet lors du transport et du stockage chez l'utilisateur final ne fait pas l'objet d'une délocalisation des émissions par défaut de connaissance des circuits et des délais de

² Enquête Annuelle des Consommations d'Energie dans l'Industrie

distribution. En conséquence, la totalité de l'émission de méthane est comptabilisée au lieu d'extraction et le charbon importé est supposé ne plus émettre sur le territoire national, excepté les émissions relatives à la combustion.

Figure 5 : Schéma relationnel des émissions liées à l'utilisation de l'énergie

Pour le pétrole et le gaz, les données proviennent du Comité Professionnel du Pétrole (CPDP) pour ce qui concerne l'extraction. Le transport et la distribution sont basés sur les ventes de certains produits pétroliers et du gaz naturel. Les quantités auto consommées (par exemple dans les stations de compression) sont estimées à partir de données de GdF et GSO.

La quantité de pétrole brut extraite sur le territoire national est marginale comparée à la quantité traitée par les raffineries. Les principaux gisements sont situés dans le Bassin Parisien et en Aquitaine.

La distribution des produits pétroliers et plus particulièrement de l'essence, entraîne des émissions atmosphériques de COV par évaporation (cf. section 2.2). La distribution de carburant couvre toutes les opérations depuis la raffinerie jusqu'au remplissage des véhicules inclus.

Le gaz naturel provient principalement des gisements situés dans le sud-ouest (plus de 90 % de la production nationale) et secondairement du bassin parisien. Cette production ne satisfait que 10% environ de la consommation aussi importe-t-on des quantités importantes de gaz naturel depuis la Russie, les Pays-Bas, l'Algérie. L'extraction, le transport, et la distribution du gaz naturel induisent des rejets de COV significatifs (principalement du méthane). Ces quantités sont cependant faibles au regard de la consommation.

Les émissions sont calculées au moyen de facteurs d'émission ainsi que de données spécifiques à l'extraction du charbon fournies par CdF.

3.1.2 / production d'électricité

La totalité de la soixantaine d'installations de production d'électricité située en Métropole et Outre-mer, hors auto producteurs, est recensée individuellement chaque année à l'occasion des inventaires d'émissions. Consommations caractéristiques des combustibles et émissions sont directement utilisées (cf. remarque 1 section 3.1.10).

A l'exception des turbines à gaz et des moteurs fixes qui ne représentent qu'une petite part de la production, toutes les installations constituent des Grandes Installations de Combustion utilisant essentiellement du charbon et du fioul lourd à basse teneur en soufre, voire ponctuellement d'autres combustibles tels que gaz de haut-fourneau, gaz de cokerie, gaz naturel.

Seulement, quelques pour-cent de l'électricité sont produits par la filière thermique classique, la filière nucléaire étant prépondérante en France, et la production hydraulique non négligeable. L'auto production thermique représente environ le quart de la production de la filière thermique classique. Elle est comptabilisée dans le secteur relatif à l'activité principale des établissements producteurs (industrie, chauffage urbain, etc.).

3.1.3 / chauffage urbain

Caractéristiques et consommations des installations les plus importantes sont relevées et utilisées annuellement sur une base individuelle (cf. remarque 1 section 3.1.10). Le solde de la consommation d'énergie déduite de l'enquête annuelle réalisée par la profession est attribuée aux plus petites installations.

Plusieurs centaines d'installations de chauffage urbain sont actuellement recensées. Environ 1/6 d'entre elles appartiennent à la catégorie des Grandes Installations de Combustion et représentent à elles seules près de 40% de la capacité thermique installée. Pour ces installations comme pour la production d'électricité, une incidence notable des conditions climatiques sur les émissions est observable.

Les émissions sont estimées pour partie au moyen des résultats de mesure des émissions et pour le reste au moyen de facteurs d'émission.

Lorsque cela s'avère nécessaire, la répartition géographique des plus petites installations est réalisée au moyen d'indicateurs utilisant la population urbaine.

3.1.4 / raffinage du pétrole et du gaz

Pour les besoins des inventaires, les 15 installations concernées sont étudiées individuellement, les informations étant collectées auprès des DRIRE ainsi que de la profession. Les données spécifiques recueillies, dont caractéristiques de consommations d'énergie et émissions font partie, sont utilisées directement (cf. remarque 1 section 3.1.10). Pour les émissions non liées à l'utilisation directe de l'énergie se reporter à la section 3.2.1).

3.1.5 / transformation des combustibles minéraux solides

Les consommations et les émissions des installations minières et sidérurgiques, en particulier des cokeries, sont estimées à partir des bilans fournis par CdF, la FFA et les DRIRE, ainsi que par l'utilisation de facteurs d'émission.

3.1.6 / industrie (y compris sidérurgie, IAA, sciage et installations frigorifiques)

Pour estimer les émissions de ce secteur, la connaissance des divers emplois de l'énergie est nécessaire. Une part importante de l'énergie fossile n'est pas utilisée à des fins énergétiques ou l'est indirectement. Les quantités d'énergie sont estimées sur les bases suivantes :

- a) enquêtes annuelles (EACEI) réalisées par le SESSI et le SCEES (Agreste). Ces enquêtes proposent des statistiques selon une structure d'usages qui a été modifiée plusieurs fois au fil du temps, et qui s'avère peu appropriée à des applications dans le domaine de l'environnement. Cependant, cette série détaillée et disponible sur une période assez longue s'avère très utile.
- b) inventaire GIC dans lequel sont recensées, sur une base individuelle, consommations et caractéristiques spécifiques d'environ 160 installations appartenant à l'industrie (cf. remarque 1

section 3.1.10).

- c) données collectées auprès des DRIRE et des industriels (exploitants, organisations professionnelles), soit pour certaines installations fortes consommatrices d'énergie, soit pour des secteurs particuliers (cf. remarque 1 section 3.1.10).
- d) Eurostat, CEREN et Observatoire de l'Energie pour certaines données (biomasse, utilisation non énergétique des combustibles).

La quantité d'énergie attribuée aux procédés énergétiques industriels est estimée au moyen de ratios relatifs à la consommation d'énergie / quantité de produit fabriqué. Pour cela il est fait appel notamment à des données du SESSI ou de certaines branches par exemple la FFA.

Le solde de la quantité d'énergie consommée dans l'industrie après déduction des quantités attribuées aux Grandes Installations de Combustion, aux procédés consommant de l'énergie ("combustion avec contact") et aux usages particuliers (par exemple les machines et engins) est alloué aux plus petites installations (< 50 MW).

A noter que les consommations identifiées de certains produits utilisés à des fins énergétiques (solvants, gaz de raffinerie, biogaz, hydrogène, lubrifiants, déchets, gaz de cokerie, gaz de haut fourneau, gaz d'aciérie) viennent, dans certains cas, en déduction des quantités obtenues précédemment pour éviter des doubles comptages (par exemple, liqueur noire avec biomasse).

La distribution géographique des émissions est effectuée au moyen de procédures développées à cet effet à partir des statistiques de consommation d'énergie dans l'industrie.

3.1.7 / résidentiel/tertiaire

Les consommations d'énergie de ce secteur sont appréciées à partir des données de l'Observatoire de l'Energie et du CEREN; la ventilation des produits pétroliers est donnée par le CPDP. La différence constatée entre les données du CPDP et de l'Observatoire de l'Energie correspond d'une part, à la majeure partie du chauffage urbain (le solde affectant l'industrie et marginalement l'agriculture) et d'autre part, aux usages militaires dont la décomposition en divers sous-produits est confidentielle.

Le secteur résidentiel/tertiaire regroupe d'une part, de multiples consommateurs d'énergie de types très différents :

- bureaux, commerces, hôpitaux, universités, centres d'essais, etc.
- foyers domestiques (chauffage, eau chaude, cuisine, agrément).

et d'autre part, une grande diversité d'équipements thermiques :

- chaudière de type industriel,
- chaudière domestique de tous types,
- chauffe bain,
- chauffe eau,
- poêle,
- cheminée à foyer ouvert ou fermé,
- appareil de cuisson,
- etc.

Les émissions sont estimées à partir des statistiques énergétiques et de facteurs d'émission spécifiques à chaque combustible en s'efforçant de tenir compte de la diversité des équipements utilisés. La dizaine d'installations appartenant à la catégorie des Grandes Installations de Combustion

Combustion sans contact et avec contact

Les procédés utilisant de l'énergie appartiennent à l'un ou l'autre cas :

- les sources relatives à la "combustion sans contact" (chaudières, TAG, moteurs, certains fours, panneaux radiants, etc.) c'est-à-dire aux procédés dans lesquels la flamme où les produits de la combustion ne sont pas en contact avec un produit tiers. Ces émissions sont alors estimées directement à partir des consommations d'énergie.
- les sources relatives à la "combustion avec contact", c'est-à-dire aux procédés dans lesquels la flamme ou les produits de la combustion entrent en contact avec un produit tiers (fours à clinker, à verre, métallurgique, etc.). Dans ce cas, les émissions sont le plus souvent estimées à partir de la quantité de produit fabriqué, car diverses réactions sont susceptibles de modifier qualitativement et quantitativement les rejets.

(> 50 MW) est étudiée spécifiquement.

Les machines utilisées dans le secteur résidentiel (groupes électrogènes, machines de jardinage, etc.) font l'objet d'estimations forfaitaires de consommations d'énergie auxquelles sont associées des facteurs d'émission particuliers.

3.1.8 / agriculture

Les consommations d'énergie proviennent de l'Observatoire de l'Energie et pour la ventilation des produits pétroliers, du CPDP. La consommation de bois est évaluée à partir d'une étude datant de 1985 publiée par l'Observatoire de l'Energie.

Seuls les usages spécifiques de l'agriculture sont pris en compte (chauffage des serres, conservation du lait, chauffage pour l'élevage, etc.) tandis que la consommation d'énergie domestique est incluse dans le secteur résidentiel. Le FOD et l'essence sont supposés être utilisés en totalité par les machines (tracteurs, moissonneuses, etc.).

Comme pour le secteur précédent, les émissions sont déterminées à partir de statistiques énergétiques et de facteurs d'émission appropriés, tant pour les sources fixes que pour les machines mobiles.

3.1.9 / transports

Les consommations de produits pétroliers des différents modes sont données par les statistiques du CPDP et de la CCTN. Ces données sont en accord avec celles de l'Observatoire de l'Energie.

Cependant, des considérations particulières sont introduites :

- dans le cas du trafic maritime, le champ couvert correspond au trafic entre deux ports français à l'intérieur de la zone EMEP.
- dans le cas du trafic aérien, le champ couvert par le total national varie selon les inventaires (trafic aérien < 1000 m seulement y compris trafic international pour UNECE [sauf CO₂ comme UNFCCC], trafic domestique seul y compris la croisière (partie du vol au-dessus de 1000 m) pour UNFCCC). Pour le trafic aérien, les statistiques des ventes totales de carburant sont disponibles (CPDP), sans distinction des vols domestiques et internationaux.
- dans le cas des transports routiers, selon les spécifications de l'UNFCCC, les consommations de carburants correspondent aux quantités livrées pour ce secteur. Ces données sont issues des statistiques du Ministère des Transports (Commission des Comptes des Transports de la Nation). Cette est appliquée de la même manière aux inventaires établis pour UNECE seules les ventes sur le territoire national sont prises en compte. Voir la section 3.3 pour plus de détail concernant les éléments relatifs au calcul des émissions.

3.1.10 / remarques relatives au bilan énergétique

Remarque 1

La comparaison de l'approche de référence basée sur les bilans énergétiques avec l'approche sectorielle, conduit à un écart inférieur à 2 % sur le CO₂-somme des consommations d'énergie obtenue avec l'approche sectorielle utilisée dans l'élaboration des inventaires peut être comparée au bilan énergétique national produit par l'Observatoire de l'Energie. Un écart très faible inférieur à 2 % est constaté. Les raisons en sont principalement :

- la prise en compte des caractéristiques réelles des combustibles par rapport à des caractéristiques standard.
- les approximations des différents éléments respectifs de l'inventaire et du bilan énergétique, notamment les ajustements statistiques.

Remarque 2

La différenciation des consommations d'énergie selon la nature des équipements est importante du point de vue de l'environnement car :

- les émissions de nombreuses substances (NOx, COV, CO, etc.) dépendent des techniques utilisées (un moteur ne produit pas la même quantité de NOx qu'une turbine ou une chaudière pour

une même quantité d'énergie consommée). Les cas du CO₂, voire du SO₂ pour lesquels il est possible en première approximation de s'affranchir de cette contrainte, tendent à faire oublier cet aspect important dans la réalisation des inventaires.

- les directives, conventions, et plus généralement les spécifications relatives à la présentation des résultats, nécessitent de fournir des estimations pour certaines catégories d'installations (par exemple la directive GIC³ 88/609 exclut moteurs, turbines et la plupart des fours). Il en résulte la nécessité de segmenter certaines sources en fonction de critères particuliers dans les inventaires.

Remarque 3

Des progrès restent à faire pour une meilleure prise en compte des quantités d'énergie fossile du point de vue des émissions dans l'atmosphère, en particulier en ce qui concerne les usages, la nature des équipements et le détail des produits valorisés énergétiquement.

Au plan global, l'incertitude sur les consommations d'énergie est faible et reste largement inférieure aux incertitudes relatives à la détermination des émissions (sauf pour CO₂ et SO₂ qui sont probablement du même ordre de grandeur).

3.2 / procédés non énergétiques hors agriculture et nature

Contrairement à ce que peut laisser croire le titre de cette section, quelques uns des procédés appartenant à cette catégorie ont une relation avec l'énergie. Le plus souvent, celle-ci se présente sous forme de vapeur produite dans des installations de combustion classiques distinctes (cf. section 3.1), ou par l'intermédiaire de certains produits comme l'oxygène. Une partie de la matière première peut aussi participer à des réactions thermiques. Cependant, les processus mis en œuvre diffèrent d'une combustion classique.

3.2.1 / procédés du raffinage du pétrole

Les émissions en provenance des équipements tels que vannes, joints, récupérateurs de soufre, régénération de catalyseur, stockage et manipulation d'hydrocarbures, etc. sont appréciées à partir de données spécifiques à chaque installation de chacune des raffineries.

3.2.2 / procédés de la sidérurgie, de la transformation de l'acier et des cokeries

Les sources considérées dans cette section sont à l'origine en grande partie des émissions fugitives (extinction du coke, chaîne d'agglomération, chargement des hauts-fourneaux, coulée de la fonte, aciéries à l'oxygène et électriques, laminoirs). Les données proviennent des statistiques relatives à ces secteurs et de diverses sources pour les facteurs d'émissions.

3.2.3 / procédés des industries des métaux non-ferreux

Les émissions des secteurs d'activité couverts sont déterminées à l'exception de quelques uns à partir de statistiques de production et de facteurs d'émission spécifiques.

3.2.4 / procédés de la chimie

La fabrication de plusieurs dizaines de produits différents est prise en compte. Le plus souvent c'est le fait d'un nombre limité de sites comportant assez fréquemment différents ateliers relatifs à divers procédés. Les productions et/ou les quantités de matière première consommées sont collectées dans une grande majorité de cas sur une base individuelle. Elles sont complétées par des estimations à partir de statistiques nationales ou de capacités installées. Les émissions sont estimées en tenant compte, si nécessaire, des spécificités de chaque installation et éventuellement sur la base de facteurs d'émission lorsque une connaissance plus précise fait défaut (par exemple ceux de la chimie organique et de la chimie inorganique).

3.2.5 / matériaux minéraux, pâte à papier, construction automobile

Comme précédemment, ces secteurs comportent un nombre suffisamment restreint d'établissements pour autoriser une approche individuelle en terme de quantités produites ou mises en œuvre (tout au

³ Grandes Installations de Combustion

plus deux ou trois dizaines chacun) et permettre la prise en compte de données spécifiques telles que mesure des émissions, type de procédé, etc. Pour certaines installations ou substances des facteurs d'émission sont utilisés à défaut d'une connaissance plus précise.

Ce dernier raisonnement s'applique particulièrement à la production de pâte à papier, à la décarbonatation (chaux, ciment, verre) et à l'évaporation de solvants dans la peinture automobile.

3.2.6 / autres procédés industriels

A l'inverse de la plupart des secteurs évoqués précédemment dans les sous-sections 3.2.x, il existe de nombreuses activités pour lesquelles :

- les installations sont unitairement de petite taille ou de moindre importance relativement aux rejets dans l'atmosphère : fabrication de panneaux de particules, fabrication de produits alimentaires (pain, vin, bière, alcools), carrosserie, construction de bateaux, prélaquage, nettoyage à sec, mise en œuvre de divers produits (polyester, PVC, polyuréthane, mousse de polystyrène, caoutchouc), fabrication de produits adhésifs, finition textile, tannage du cuir, imprimerie, traitement du bois, etc.
- voire très disséminées dans différents secteurs industriels : recouvrement de surfaces par de l'asphalte ou par de la peinture, dégraissage des métaux, application de colle, etc.
- l'estimation des rejets de ces activités passe le plus souvent par l'utilisation de statistiques nationales auxquelles sont associées des facteurs d'émission qui s'efforcent de tenir compte de l'évolution des caractéristiques des produits et des techniques utilisées, lesquelles évoluent au cours du temps.

A l'exception de quelques activités (extraction d'huiles comestibles et non comestibles, prélaquage, etc.) pour lesquelles une approche plus fine est parfois possible, la distribution géographique des émissions est effectuée au moyen d'indicateurs tels que le nombre d'employés ou la consommation d'énergie.

3.2.7. / procédés du secteur résidentiel/tertiaire

Les émissions sont généralement estimées à partir de coefficients basés sur la population. Les activités du secteur résidentiel et tertiaire couvrent aussi l'utilisation de peintures et autres produits à base de solvants, la consommation de produits pharmaceutiques, l'emploi du protoxyde d'azote en milieu hospitalier, réfrigération, aérosols, extincteurs, climatisation, etc.

3.2.8 / traitement des déchets

Le traitement des déchets concerne différents secteurs et différents procédés :

- l'incinération se décompose en plusieurs sous activités
- ✓ incinération des déchets ménagers (environ 300 installations)
- ✓ incinération de déchets industriels en tant qu'activité spécifique (environ 20 installations)
- ✓ incinération de déchets industriels en tant que procédé connexe à une autre activité principale (torchères, incinérateurs)
- ✓ incinération de déchets particuliers (déchets hospitaliers, boues de stations d'épuration des eaux, carcasses)
- ✓ crémation (environ 70 installations).

Dans la quasi totalité des cas, les installations d'incinération sont répertoriées sur une base individuelle et leurs émissions évaluées à partir des quantités traitées et de facteurs d'émission lorsque les émissions ne sont pas directement connues.

Les feux ouverts sont supposés négligeables faute de données précises.

- la mise en décharge des déchets est inventoriée par l'ADEME⁴ ; on dénombre environ 500 installations, nombre en recul progressif par suite des actions engagées dans ce secteur. L'ensemble des données et hypothèses utilisées sont établies en concertation avec l'ADEME. Les émissions sont estimées sur la base de facteurs d'émission relatifs à différents critères :

⁴ Agence de l'Environnement et de la Maîtrise de l'Energie

- ✓ la dégradation progressive des déchets basée sur une cinétique d'ordre 1 (GIEC tier 2).
- ✓ le type de déchet selon leur biodégradabilité
- ✓ le type de décharge (avec ou sans compactage)
- ✓ la récupération et l'utilisation du biogaz (brûlage en torchère ou valorisation thermique).
- les autres traitements tels que le traitement des eaux, l'épandage des boues, le compostage, la fabrication de biogaz ou de produits énergétiques dérivés, etc. sont abordés à partir de statistiques globales et de facteurs d'émission assez imprécis. La répartition géographique est réalisée à partir des recensements existants et/ou au moyen de valeurs supplémentaires comme la population.

3.3 / transports

Les différents modes de transports appartiennent à l'ensemble des sources mobiles. Ce dernier englobe également des engins mobiles utilisés dans d'autres secteurs : véhicules spéciaux (grues auto-portées, pelleteuses, engins de déneigement, etc.), tracteurs agricoles et forestiers, compresseurs de chantier, groupes électrogènes, etc.

3.3.1 / transport routier

Les émissions des véhicules routiers dépendent de nombreux paramètres en rapport avec :

- les caractéristiques du véhicule (voiture particulière, véhicule utilitaire léger, poids lourd, deux roues)
- ✓ le type de véhicule,
- ✓ la motorisation et le carburant (essence, gazole, GPL-c, GNV),
- ✓ les équipements (pot catalytique, climatisation, type de réservoir, injection),
- ✓ l'âge.
- les conditions d'utilisation
- ✓ le parcours annuel,
- ✓ la longueur moyenne d'un trajet,
- ✓ les réseaux empruntés (autoroute, route, urbain) qui conditionnent pour partie les vitesses de circulation,
- ✓ les conditions climatiques,
- ✓ l'entretien du véhicule,
- ✓ le comportement de l'utilisateur (conduite sportive, charge du véhicule, etc.).

Les émissions sont déterminées au moyen du modèle européen COPERT⁵ à partir d'une estimation du parc de véhicules provenant de la base de données OPALe (Ordonnancement du PArc en Liaison avec les Emissions), d'un ensemble d'hypothèses relatives aux conditions d'utilisation et de fonctions de consommations et d'émissions, ainsi que d'un ensemble de statistiques sur le bilan de la circulation routière en France issu de la Commission des Comptes des Transports de la Nation. La figure 6 en présente le principe, à savoir :

- **dans un premier temps, la détermination des données de base.** Le parc OPALe fait appel à diverses sources statistiques CCFA⁶, ARGUS, FIEV⁷, Ministère des Transports. Les parcours annuels, les longueurs de trajet, la répartition du trafic sur les différents réseaux sont fixés à partir de diverses sources (INRETS⁸, ADEME, CCTN⁹, etc.). Les consommations de carburants proviennent de la CCTN.
- **dans un deuxième temps le calcul des consommations totales.** Les consommations totales sont calculées à partir des données initiales au moyen des fonctions proposées par le modèle. Ces fonctions sont établies sur la base d'un nombre important de mesures réalisées par divers laboratoires européens. Les consommations calculées sont comparées aux consommations de référence et une démarche itérative conduit à ajuster les données initiales.

Remarque : Un minimum de degrés de liberté est nécessaire pour permettre les ajustements. Ceux-ci sont effectués différemment selon les types de véhicule de manière à conserver un maximum de cohérence avec les données de la CCTN.

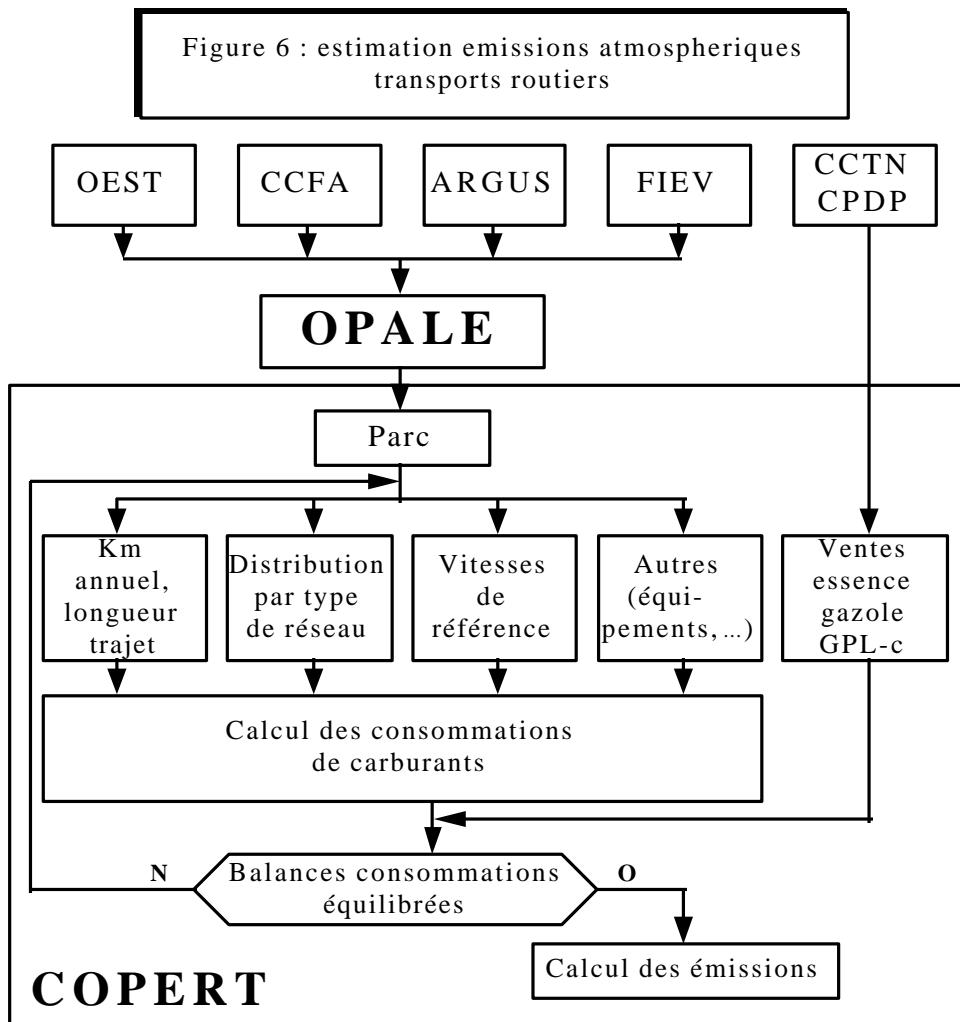

⁵ COnputer Programme to calculate Emissions from Road Traffic

⁶ Comité des Constructeurs Français d'Automobiles

⁷ Fédération des Industries des Equipements pour Véhicules

⁸ Institut National de REcherche sur les Transports et leur Sécurité

⁹ Commission des Comptes des Transports de la Nation

- **dans un troisième temps le calcul des émissions.** Les émissions sont calculées sauf dans quelques cas au moyen des fonctions d'émissions unitaires proposées par le modèle COPERT. Ces dernières sont basées sur un nombre important de mesures réalisées par divers laboratoires européens dont l'INRETS en France.

Pour mémoire, en cas de résolution spatiale plus fine, les émissions sont calculées en faisant appel à des procédures complexes basées sur divers paramètres : trafic sur différents réseaux, effets de transit aux frontières, données socio-économiques (population urbaine, rurale, infrastructure routière, etc.).

3.3.2 / transport ferroviaire

Les émissions sont déterminées sur la base des consommations d'énergie de ce secteur et de facteurs d'émission.

3.3.3 / transport fluvial

Les émissions sont déterminées sur la base des consommations d'énergie de ce secteur et de facteurs d'émission.

3.3.4 / transport maritime

Le trafic international est généralement exclu du champ national mais constitue une partie des inventaires rapportée séparément.

La part du trafic national est définie comme le trafic effectué entre deux ports situés dans un même pays à l'intérieur de la zone EMEP (approximativement l'Europe). Ainsi la liaison Le Havre - Ajaccio est comptabilisé dans les émissions françaises, même si les rejets se produisent en partie loin de France. A l'inverse, les émissions d'un ferry reliant Douvres et Calais ne sont pas incluses dans le total national.

Les émissions dues au trafic national sont déterminées sur la base de la part de consommation d'énergie correspondant au trafic défini ci-dessus. Une étude réalisée par le CITEPA à partir des trafics portuaires et de considérations relatives aux différents types et tailles de bateaux conduit à un ratio de l'ordre de 4% des soutes nationales.

La pêche est intégralement prise en compte par l'intermédiaire de la consommation d'énergie de ce secteur quels que soient les lieux de pêche même très éloignés.

3.3.5 / transport aérien

Dans le cas du trafic aérien, sont prises en compte dans les totaux nationaux :

- les émissions produites au-dessous de 1000 m pour UNECE quelles que soient les vols et les compagnies.
- les émissions du trafic domestique pour UNFCCC quelles que soient les compagnies.

La définition du trafic domestique s'entend comme pour les bateaux comme correspondant au trafic entre deux aéroports d'un même pays.

Les émissions hors total national (au-dessus de 1000 m ou internationales selon les cas) sont calculées mais rapportées séparément.

Les émissions sont estimées à partir d'une méthode détaillée basée sur les mouvements du trafic commercial et du trafic non commercial (sources DGAC¹⁰), sur les données OACI¹¹ et sur les éléments méthodologiques de MEET¹² et de CORINAIR. Pour chaque liaison, la méthode mise en œuvre prend en compte le type d'avion et le type de moteur ainsi que les diverses caractéristiques du vol dont les consommations au cours des différentes phases (roulage au sol, décollage, montée, croisière, approche, atterrissage). Le bouclage énergétique sur la vente totale de carburant pour aéronefs est assurée en déterminant la consommation de la phase de croisière internationale comme égale à la différence entre le total des ventes et la consommation calculée, d'une part, pour la phase LTO domestique et, d'autre part, pour la phase de croisière domestique.

3.4 / agriculture et sylviculture

3.4.1 / élevage

De cette activité résulte des quantités importantes de méthane et d'ammoniac notamment. Les estimations sont effectuées au moyen des statistiques relatives au cheptel et de facteurs d'émission résultant de différentes hypothèses concernant les pratiques d'élevage pour chacune des douze catégories d'animaux considérées.

3.4.2 / cultures et forêts

Les surfaces occupées par les diverses espèces cultivées et les essences sont recensées par le Ministère de l'Agriculture.

En ce qui concerne le méthane, le protoxyde d'azote et l'ammoniac, les émissions sont calculées au moyen de facteurs d'émission assez rustiques. Pour les composés organiques volatils, le modèle COBRA¹³ développé par le CITEPA est utilisé. Le modèle calcule pour chaque espèce et essence les émissions sur une base mensuelle, car celles-ci dépendent de paramètres fonctions du temps comme la température et le développement de la biomasse foliaire. Pour ce faire, la France est découpée en 29 zones climatiques et les données de température tri horaires de 88 stations météorologiques sont

¹⁰ Direction Générale de l'Aviation Civile

¹¹ Organisation de l'Aviation Civile Internationale

¹² Methodologies for Estimating air Emissions from Transports

¹³ Composés Organiques de la Biomasse Rejetés dans l'Atmosphère

intégrées. In fine, le modèle COBRA fournit des émissions par type d'espèce et par département. Ces dernières restent associées à des incertitudes importantes.

3.4.3 / changement dans l'utilisation des sols / puits

Cette section n'a d'intérêt que pour la détermination des émissions de CO₂ qui requiert de tenir compte du puits de dioxyde de carbone que représente la photosynthèse.

A cet effet, la méthode préconisée par le GIEC consiste à déterminer d'une part, les **accroissements de biomasse** au cours de l'année étudiée et, d'autre part, l'utilisation de la biomasse à partir de l'évaluation qualitative et quantitative des différents **produits issus des récoltes** (houppiers, bois de sciage, bois de feu, fourrages, etc.). Selon les usages de ces produits, le stock de carbone constitué par l'accroissement de biomasse de l'année considérée est réduit de la quantité de carbone relative aux émissions de CO₂ dues à la combustion de la biomasse et majoré où réduit de l'accroissement ou de la perte de carbone des sols dans la mesure où leur utilisation a été modifiée.

Emissions anthropiques et naturelles

A y regarder de près, cette distinction n'est guère aisée. Si pour les volcans, les hydrates de gaz, les termites, etc. on peut à peu près affirmer que les rejets dans l'atmosphère sont sans relation avec la main de l'homme, cela est beaucoup plus discutable en ce qui concerne les forêts, les animaux, l'utilisation des sols (canaux, lacs, fossés, marais, etc.). Les experts s'accordent à dire qu'une part importante des émissions de ces sources est liée à l'activité humaine. Cette part est assez difficilement quantifiable, de même que les émissions de ces sources prises globalement.

De plus, ces émetteurs se caractérisent par le fait que l'homme peut difficilement prétendre agir pour les modifier significativement dans des délais de temps comparables à ceux généralement considérés en matière de planification (quelques dizaines d'année).

C'est pourquoi ces émetteurs tendent à être classés à part et, de ce fait, leurs émissions n'entrent pas dans les émissions de référence retenues dans le cadre des conventions internationales.

Cependant, ces émissions interviennent dans les phénomènes de pollution de l'air : COV biogènes en rapport avec la formation d'ozone troposphérique, puits de CO₂, CH₄ de l'anaérobiose, pour l'effet de serre, etc.

3.5 / autres sources

Les émissions des autres sources, quelles soient considérées naturelles ou anthropiques, ne sont pas rapportées dans l'inventaire UNFCCC, à l'exception des émissions biogènes des forêts. Lorsqu'elles sont rapportées, notamment dans l'inventaire UNECE, elles sont estimées au moyen de facteurs d'émission et couvrent différents types d'émetteurs dont les principaux sont :

- les forêts qui sont couvertes par le modèle COBRA (cf. section 3.4.3). La distinction entre sources anthropiques / naturelles repose sur les superficies gérées par l'homme (95 % en Métropole),
- les prairies naturelles incluses également dans COBRA et définies comme telles par le Ministère de l'Agriculture,
- les feux de forêts même d'origine criminelle ou accidentelle d'importance très variable selon les années (73 000 ha en 1990, 19 000 en 1998 en métropole),
- les zones marécageuses qui regroupent les marais et étangs soit respectivement 95 000 ha et 30 000 ha en métropole.
- les eaux libres pour lesquelles l'inventaire porte sur les lacs, marais salants, rivières et canaux couvrant respectivement en métropole 347 000 ha, 90 000 ha et 330 000 ha.
- les animaux sauvages, les émissions de CH₄ des termites et des mammifères sont négligées faute d'information.
- les volcans (inactifs en France métropolitaine) mais négligés en outre-mer faute d'information fiable et d'un besoin de couvrir ce type de source.
- les hydrates de gaz proches de la surface du sol peu répandus sur le territoire national sont supposés ne pas contribuer aux émissions de méthane.

NOTE : Les émissions de CO₂ provenant de la respiration des êtres vivants (homme, mammifères, etc.) ne sont pas prises en compte, un certain état d'équilibre étant supposé. L'ordre de grandeur est estimé approximativement à 100 Mt de CO₂, soit environ entre un cinquième et un quart des autres émissions anthropiques.

annexe 4 – fichiers informatiques relatifs au texte, tableaux et figures du rapport

Le rapport intégral est disponible sur le site web du CITEPA à l'adresse <http://citepa.org>

Le support informatique éventuellement joint au rapport contient les éléments suivants :

Texte du rapport

Les fichiers "UNFCCC_France_dec2000a" et "UNFCCC_France_dec2000b" (Word 97) contiennent respectivement le corps du texte et les annexes à l'exclusion des tables du CRF.

Tables CRF du format UNFCCC.

Les fichiers "CRF_France_xx" (Excel 2000) contiennent les tableaux de données au format UNFCCC relatifs à chacune des années considérées. Les deux derniers caractères du nom correspondent à l'année de référence (exemple CRF_France_90 pour l'année 1990). Chaque fichier comporte 61 feuillets qui correspondent aux tableaux définis dans le CRF et pour la plupart reproduits dans l'annexe 1.

Les tableaux de données relatifs d'une part à la France métropolitaine et d'autre part aux départements et territoires d'outre-mer sont disponibles séparément.

Tableaux et figures du rapport.

Les tableaux de synthèse et les figures présents dans le corps du rapport se trouvent dans le fichier "serre_dec2000" (Excel 97). Ce fichier comporte 16 feuillets :

- le feuillet "comp-meth" correspond au tableau page 13 du rapport.
- le feuillet "recap" correspond aux tableaux et figures des pages 17, 19, 20 et 19 du rapport.
- le feuillet "résumé" correspond à la page 6 du rapport
- le feuillet "HFC_PFC_SF₆" correspond au tableau de la page 16 du rapport.
- le feuillet "secteurs" correspond à la page 24 du rapport.
- le feuillet "graph_var" correspond à la page 18 du rapport.
- le feuillet "appro-référ" correspond au tableau page 22 du rapport.
- le feuillet "réfé-annexe" correspond au tableau à la page 23 du rapport.
- les feuillets "CO₂, CH₄, N₂O, SO₂, NO_x, COVNM, CO" correspondent aux tableaux pages 25 à 31 du rapport.
- le feuillet "dispo table CRF" correspond au tableau de l'annexe 4
- le feuillet « IPCC96-SNAP97 » correspond à l'annexe 2 du rapport.

DISPONIBILITE DES TABLES CRF

- Les tables CRF dans le rapport UNFCCC sont données en annexe, seules les tables des années 1990, 1998 et 1999 y figurent.
- Les tables concernant le recalcul des émissions pour les différentes années 1990 à 1998 (les tables 8) sont incluses dans le CRF 1999 uniquement.
- CRF des autres années.
- ces années intermédiaires, cf. tableau ci-après.

N.B.: normalement en régime établi, seules les tables CRF de la dernière année sont requises.
